DIGEST MONTHLY

FOOD IN A BALLOON

THE latest transparent food wrap is rub ber, and it has fulfilled its principal purpose long before it reaches the cetallers' shelves, with its sales appeal 'purely concidental," according to the Industrial Bul-

letin of Arthur D Little, Inc. The name Cryovae will be recognizable to our classical race of food venders as possibly meaning "cold and empty" Such an unorthodox trade name is descriptive of the

Vacuum nacking -in a balloon

history of the new wrap before it is put on sale. In its original form it resembles a deflated, wide mouthed toy balloon. It is blown up, however, by stretching the web mouth over a frame and drawing a vacuum around the outside. It thus takes the shape of the cylindrical container into which it has been drawn and the chilled sides of the contamer "freeze" it into the larger size. Into such an open-end package is dropped a broder, a vacoum bose removes the inside air and draws the wrap close to the contents, then the neck of the balloon is twisted and clamped to make the whole vacuum pack air-tight Then comes the trick the package is immersed in warm water to "thaw" the balloon, it attempts to shrink to its original size, and stretches to a tant, transparent wrap around the plump chicken

Various potential advantages for such a food container are obvious, and Dewey and

Almy claim to have realized many of them without most of the possible objections. A special latex rubber was necessary, with no sulfin. Special equipment was designed to reduce the handling time in packaging to a nomt well lo bow that for many other wran-Formulas and production technique devel oped in the manufactors of latex sounding balloons were required for the necessary low cost, strength, and so forth bleidentally, in the chilled, expanded form, the rubber has surprisingly great strougth. Most of the advantages claimed are due to the chimination of an or to the complete moistnee tightness Pork products, for example, are said not to develop rancialty in the fat, clinkens to show no "freezer burn," the bane of low temperature preservation of poultry Prevention of moisture loss not only preserves the original weight, but reduces frosting of cool ing coils in the p frigorating units, and in reases their freezing efficiency

Bags for poultry are designed as one trip outainers to be removed by the consumer Larger bags are intended for the storage of scasonal surpluses of green hams, pork louis, and the like, which are temporarily frozen and released for the market as needed. For these purposes, the latex bags can be washed, shrunk and reused several times. The largest bags are being designed for use with quarters of beef, yeal, and lamb careasses, and are expected to find their principal market in the export field A big for a 350-pound side of best is said to be a practical possi-

RUBBER LUBRICANT

MAY (ERINE has been proved to be an J perior to mineral oil lubricants for rubber tubes and other rubber prices for surgical use by a long series of severe tests Comparison between mineral oil and glycerine was made by coating tubes with each of these fluids, washing with some solution

Conducted by F. D. Me HUGH after five minutes, ruising with water and hually boding five minutes to sterilize them Rubber takes labracated with oil were no fit for use after 37 such cycles. After 200 builings, those lubricated with glycerine were still firm and usable. The bibricating action of each is satisfactory -- D. H. K.

PILOT VALVE

NEW industrial development by Schrader's Son, known as the Pilot Valve, is designed to give a delayed or probuged blast of air for ejecting work from a press, after the ram has stopped its opward motion, it is especially usoful on manually fed presses using overhead knockout or compound dies

The duration of the air blast may be regu lated by a simple serow adjustment on the valve It is easy to serve e and saves money by conserving air and channating the necessity of interchanging machine parts to achieve the results of a timed blast of air With vent closed, it may be used as an air control valve on any mechanism

TENSION WRENCH WITH FLASH SIGNAL

[N the assembly of many products, and particularly in the automobile industry, it is often necessary to tighten unts and holts to a uniform tension. Wrenches with needle gages and others which produce a click when a certain tension is reached have been used in the past, but both types have their disadvantages in dark or noisy corners of factories. The Blackbawk Mann facturing Company solves this problem with a wrench called the Torkflash, which flashes

When the correct pre-set is applied to the handle of this new wrench, a signal light flash-

a signal light when the pre-set tension is

No mathematics is necessary to operate this wreach as the required tension is easily set by the five-in-one scale which slips over the cylinder enclosing the flash-light as-embly at the base of the handle grap. This cylinder is rotated by finger pressure to show desired scale.

Torkfissh has been tested at a capacity raing of 1400 inch-pounds for 870,00 mechanical pulls without affecting accuracy or strength of the wrench up to that point. Used at the usual range of 800 inch-pounds, it has been tested over 130,000 times and full accuracy has continued after that point.

ICE-COOLED MACHINE GUNS

N EWEST use for dry ice is as a coolant for machine guns A detachable jacket, filled with dry ice and slipped over the barrel, keeps the gun continuously cool The scheme enables fighting planes and bombers to carry fewer guns, yel to maintain continuous fire.

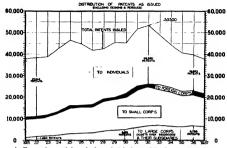

To Develop a LIFETIME TIRE

WITH child sized machines, serutists of the Fisk Tire Company are working in a miniature rubber plant to perfect the tire of the future that will carry automobiles along super-highways at 100 miles per hour

The musture plant duplicates in every detail the grant featory methods used in standard manufacture. There are hus of compounds, mills and calenders for musing tubber, a series of vulcanuers and preservable and the series of successive and preservable of the series of

Purpose of the miniature plant is to facilitate research work, speed operations by working with small quantities, and climinate unnecessary waste.

Today these scientists are looking toward 1950. The future tire, they say, will be lighter and tougher, with greatly improved safety features. The careass will be stronger to stand greater temperatures of high-speed operation. With decreased weight through

An illuminating graph from the Journal of the Patent Office Society, which shows the total number of patents issued during each year, from 1921 through 1977. The distribution of these patents between individuals and responsitions is particularly striking. It will be noted that, despite the impression that large corporations are obtaining the preponderance of patents issued doaty, their percentage is relatively small in comparison with the number of patents issued to small progressive cosporations as well as to individual inventors

redistribution of materials and through improved materials, greater flexibility will be secured, which in turn will provide better riding and wearing qualities. Treads will be tougher to stand up under increased mileage.

Eventually, they say, a tire will be made to last the lifetime of the car. In the meaning, when automobiles are ready to ride express highways, tires to carry them will be waiting--tires that were developed on these bady may hims.

REJUVENATION ATTEMPTS Do Not Change Length

of Life

THE length of a person s life is set by a hereditary time-clock or power of living that is in him when he is born, Prof. A J. Carlson of the University of Chicago recently told members of the American Collège of Physicians

Contrary to the pseudo-science of rejuvenation, the sex glands are apparently not one of the links that determine the life soan of the individual. They only determine the level and duration of the reproductive period of life. Man and animals, Prof. Carlson and, would still giove old, grow feelbe, and the, presumably at the time appointed by the herdinary time-clock, even if they had no infectious diseases, as the best possible diet, lived and worked under deal conditions, and did just exactly the right amount of unital and physical work.

How work may affect the life span is largely an unwritten chapter, Prof. Carlson said. No work at all seems to lead to fatness and degeneration. Excessive physical work can spparently cause degeneration by exhausting a New Section Section 2019.

BENZOATES PRESERVE FISH

DIPPING fish fillets in a very dilute and benzastes in salt brine prologs the totarge life considerably beyond that of untreated fillets. About 0.3 percent is the concentration of benzastes in the dipping solution A dip of 30 seconds to two minutes.

The miniature rubber mill, left, being used in tire development, compared with a full-size mill, right

Above: The Tell-Tale control panel and. right, the sirplane parts that are controlled from the panci

affects only the surface of the fillet and leaves on it only about 10 percent as much benzoate as that used in the preservation of apple cuder. The same treatment has proved effective with erah and lobster meat. Food laws require that fish so treated be labeled to indicate the presence of hemostres—D HK

PAINT FOR TIRES

RECOGNIZING the present upward trend of demand for white sidewall tires. The B. F. Goodrich Company announces a new thite sidewall tire paint applicable for renewing white sidewall tires or for making present black sidewalls white.

Made with a rubber base, the new paint isself vulcanizing, is clastic and thus flexes with the tire and will not crack or elip. This new type paint is applied with a brush, dries quickly and can be washed with soap and water without affecting its original whiteness.

TELL-TALE

Title new Cutties-Wright CW-20, now newring completion, should be a fine-flivered, and splendedly equipped transport of the composition of the com

A panel of lights is placed on the instrument board. These lights are electrically connected to various vital operating parts of the plane, as indicated in one of the illustrations. The warning panel itself is shown in another illustration.

If the pilot wishes to land, he simply presses one of the ten pre-selector switches eraied wind-tunnel have resulted in an airfoil and hinge arrangement for the alleron which assures ice-free operation of this vital control. The earbureter is non-ieing, and there are both pneumatic and liquid de-ieers on the wings and tail

We hope to give a fuller description of the new craft when its flight tests have been completed. Enough has been said here to indicate that our aeronautical engineers are fully alert to the need of greater safety for our arrhers -A. K.

ANNUAL REPORT OF THE N.A.C.A.

THE complete annual report of the Na tonal Advancy (ommittee for Aeronautics contains dozens of deeply technical reports, and hundreds of printed pages A summary of the guait volume is sent in advance to the Congress of the United States. It is interesting to pick out from this summary the results of the most significant research work, as an indication of the path that eventific aeronautics is following at the

A better slotted flap has become available.

marked "Land" Lights immediately show on the Tell-Tale panel to indicate what adjustiments are necessary As the landing gar is lowered, the corresponding light goes out As landing flaps and elevators are operated, their corresponding lights disappear. When the entire panel is dark, the pilot knows that it is safe to land.

that it is safe to land.

If the pre-selector switch is directed to

Internstevas.

Rende in Fall Tale, many interesting. Besides in been incorporated in the GF-20 to reduce pilot fatigns and been the possibility of accedent. Thus, large, hubbes, upokeless wheels on all instruments assure better vision of the various disla. There is a single-movement control lever for operating fleps and landing gars. Radio systems are duplicated. The landing gear restracts in five to any except of the state of

which gives such a ligh lift eapaeity that landing speed is reduced more than ever before. The new type of flap increases lift without correspondingly increasing drag. Hence there should follow not only improved landing speed, but also improvement in take-off. A "Venetian Blind" type of flap has also been investigated, but details are not yet forthcoming.

There has been much research on the "tricyele" landing gear, also known as the nosewheel landing gear. The tricyele landing
gear has been widely adopted by constructors, but has a tendency to "shimmying."
Various experiments have been made to diminish such shimmying.
Radiators for liquid-cooled engines should

Radiators for liquid-cooled engines should no longer be of the external type which produce so much drag. If the radiator is placed within a earefully designed duct in the wing, much of the drag disappears.

In the refrigerated wind tunnel it was found that iee formation on the leading edge of the wing decreased the maximum lit coefficient from 1.32 to 0.80, and increased the drag by 50 percent. This is, unfortunately, mathematical confirmation of the serious hazards of ice formation, particularly in hastening the stall of the airplane.

In its study of engines, the Committee has confirmed by tests what practical designers have long held-that the two-stroke cycle is most attractive for the aircraft Diesel .-- A. K.

MAIL BY AUTOGIRO

RUMORS have come true, and Eastern
Air Lines has received from the Kellett Autogiro Corporation a wingless 'giro which will be used by the transport company in executing its United States mail contract covering the six-mile ferry route from the Central Airport, Camden, New Jersey, to the roof of the Philadelphia general post office,

The Kellett 'giro is a one-place ship, with a large mail compartment, and will carry all the necessary instruments for blind flying and the exacting service of roof landing The new craft is a derivative of the military 'giros which have done such excellent work with the Army Air Corps. High speed will

Mail-carrying 'giro

be 125 miles an hour, with low speed less than 25 miles an hour. The 'giro will land without forward roll and take off in less than 80 yards in still air. Specifications of the ship are span, 40 feet; useful load, 620 pounds, weight empty, 1630 pounds, pay load, 150 pounds; gross weight, 2250 pounds; fuel, 30 gallons; service ceiling, 14,000 feet; cruising range, 200 miles.-- 4 K

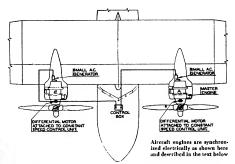

SYNCHRONIZING AIRCRAFT

ENGINES

WHEN the motors of a multi-engined airplane are out of synchronism, an annoying "beat" is produced. For example, a difference of only 20 revolutions per minute between two engines will cause a distinct "beat" every three seconds. Since it is difficult to read a tachometer to within 20 revolutions per minute, attempts by the pilot to synchronize the engines are difficult and todious. Moreover, even after the engines have been brought to the same speed by manual control, rough air or variations in operating conditions may throw them out of phase, to the renewed annoyance of the pas-

Hamilton Standard Propellers engineers have, therefore, sought to secure automatic synchronization, and have fully succeeded by a system which is both ingenious and simple in principle. When the engines are operating at approximately the same speed, the pilot merely flips a switch; the synchronizer then takes control and brings the engines to exactly the same speed and keeps them there.

A combination of mechanical and electrical principles is employed in the syn-chronizer. The actual change in speed is accomplished mechanically through adjustment of the constant-aneed control on a per-

ticular engine, by increase or decrease of the propeller pitch. But the actual adjustment of the propeller control is effected electrically and automatically by a small differential three-phase motor attached directly

to the propeller control.

The principle of operation of the differ-ential motor is that it will not rotate when the frequency of the power supplied to one of its windings is the same as the frequency supplied to the other winding Power for one winding is supplied from a small alternating-current generator driven by one engine Power to the other winding comes from another alternating-current generator driven from the "master engine". If the speed of any engine differs by as little as a single revolution per minute from the speed of the master engine, a difference of phase is created in the windings of the differential motor, and the rotor is set into motion, changing propeller pitch until all difference has disappeared

A very important feature of the differential motor is that its speed of rotation is directly proportional to the magnitude of the differences in frequency. Thus, as the engine approaches the speed of the master engine, the corrective action becomes slower Hence there is no tendency to over-shoot the mark or to produce hunting.

Manual adjustment may be obtained at any time by switching off the synchronizer, but pilots naturally prefer the automatic system of operation, and the new device has been enthusiastically received by pilots and airline operators in general .-- A K.

ANALYSIS OF LANDING

AND TAKE-OFF

N important question in transport opera-A tion is the following: "Is it or is it not safe to operate certain transport craft in and out of certain airporta?" To determine proper lengths of runways and the correct height and location of obstacles to approach or get-away, reliable information of landing and take-off characteristics under service conditions is necessary. Speaking before the Aeronautical Section of the National Safaty Council, Major A. B. McMullan, of the Civil Aeronautics Authority, described a photo-graphic system which has been developed by the Eastman Kodak Company for obtaining such vital information.

The essential equipment consists of four spring-driven motion-picture cameras with electrically operated single-frame releases. An electrical release mechanism is employed which gives absolutely correct timing. In practice, two pairs of cameras and two electrical controls are used. One pair of cameras is set on a short base of 60 feet, the other on a long base of 300 feet. With appropriate hases, markers, and so on, the airplane can be kept in view of the cameras throughout the take-off or landing process. Coordination of the films, timing devices, and so on, to-gether with a projector on which the images produced by the two cameras of a pair are projected, and which is provided with reference markers, enables complete space triangulation to be carried out A species of photographic surveying is thus accomplished The final result is that a record is obtained of the exact position of the plane in horizontal and vertical distance at any instant of time. The value of such data is obvious -A.K.

START-STOP

AMERICA operates approximately 16,000 passenger trains, and somewhere in the land a train is either starting or ending a trip

ALCOHOL HAIR TONICS PLUS MASSAGE

WHEN alcoholic preparations are used W on the scalp, vigorous brushing or massage should be used to stimulate the production of enough natural oil to offset any drying tendency they may have, according to the Journal of the American Medical As-

This statement appears in answer to a physician's query on accepted modes of treatment for falling hair.

Among the preparations suggested by the Journal for arresting acute loss of hair is a solution of cresol in alcohol. A milder form of treatment which has been the "favorite" of dermatologists for many years is a 1 percent solution of pilocarpine in 50-percent alcuhol or bay rum, according to the Journal.

"This is said to have a specific stimulating effect on the growth of hair, possibly related to its action on the vegetative nervous system."

Other formulations given by the Journal are the following chloral hydrate, from 3 to 10 percent in 50-percent alcohol or bay rum; or mercusy highloride 0.3, resortend monoacetate 6, spirit of formus acid 20, in bay rum or perfumed alcohol to make 120.

FIGURES

PUT down the figure 10, then add 88 ciphers, and you will have the amount the voice is amplified by repeaters on a telephone call between New York and San Francisco.

His origination of the center traffic strip-

Now comes Alexander L 11 Danagh, of Chicago, who submits a photograph of a section of old highway between Mexico City and Cuernavaca, Mexico, built inder the

Traffic dividing stripe on a Mexiran road built some 400 years ago

Abore. One of the sodium bombcompared with the tube in which it will be need. Right. Final stage in the production of the hombs. Filled with triple distilled sodium, they are ready to be sealed and removed

Spanish regime 350 or 400 years ago, and charly showing that the "white stripe" was in use even then

This stone road, many sections of which are in service today, being used mainly by foot travelers and light animal-drawn vehicles, has a "built in" center line of lightcolored stones.

Mr. Durraght took the photograph at a point where the did road inter-sects the new and modern highly road for each of the "winter center line" but believes at might have been put in even in the days of comparative antiquity, to prevent quarrels between those amore in targets who wanted to be sune they got their half of the toad for that butters and warms.

SODIUM BOMBS

CETTING a pinch of sodium into the sodium vapor lamp, the golden-orange lamp which is becoming increasingly common in highway highting, is a complex problem, the solution of which involves the explosion of a "homb' smaller than a marble-

The solum lamp consists of an evacuated inbular bulb with an electrode at each end. When the current is turned on, the sodium, showing as a mitror like deposit when the bulb is cold, is vaporated and becomes the current conductor, giving the bulb is characteristic golden-orangic cold.

The problem is to get the required amount of pure sodium—about 180 ounce—mode the vacuum tube without exporting the sodium to sir. A tmy bomb, a glass built containing pure sodium, does the trick, Making the mustature bombs is a complicated process in itself. Before being seafed within the min attrace bomb, the sodium undergoes a triple distillation. Attached to the fourthwester at the containing the sodium in the sodium in the sodium in the problem of the sodium in the problem of the sodium in the sodium is released into the system to force the sodium from the needs down into the bubb. Heat

is then applied to the necks to seal off the bulbs and remove them.

After the sodium bomb has been placed in the lamp tube and the tube has been evacuated, a high frequency coil is placed around the tube. This coil induces heat in any metal within the tube, by a sort of "wireless" or radio process it causes the sodium unside to nell, to heat still further to the boiling point, and to explode its glass bond and to explode its glass bond.

The sodium is this deposited on the wallof the lamp. Its glass case is shattered by the explosion into countless pieces. Since the glass case of the loom is at the most six thousandits of an inch thick, the shattered pieces are hardly more than dust, which can be left in the lamp.

Before the miniature homb explosion method was developed in the General Electric Company's Research Laboratory, the sodium was distilled separately into each lamp.

ON MAKING FEATHER DUSTERS

This recovery and me of feathers has vast quantities of them have been diverted to warnous uns—including feather disters to warnous uns—including feather disters the strong of the stro

harder metals were tried—several types of steels, then Stellite, then Carholoy. As none was entirely satisfactory, he asked for suggestions from an ingenious worker in metals.

The successful solution was an exact reversal of the direction in which previous attempts were made. Little is known of the ultimate nature of friction, and the term "hardness" is all but meaningless without a description of the manner of its measurement or the nature of the opposing forces. Hardness as measured by penetration of a steel ball may have no relation to hardness measured by depth of groove under a diamond cutter. It is therefore difficult to predict wear or friction with unusual materials or conditions, The microscopic surface of feathers presents an unusual combination of abrasive properties of surface, composition, and shape. Rubbed against what the inventor called "hrute hardness," numute particles of metal wore away, whereas lead, not rigid, hut pliable, apparently flowed back and forth under the pressure of the feather surface Lead was proposed and pure lead rings now wear almost indefinitely -The Industrial Bulletin of Arthur D Little, Inc.

ELECTRICITY COST

THE electric current consumed during its lifetime by an ordinary 15-cent, 60-wat electric lamp costs at least ten times as much as the lamp itself. Hence, even a 1 percent increase in the efficiency of a lamp will make a sizeable difference in its ultimate cost.

PRE-CAST CONCRETE SHAPES

PITTSBURGH, the city that gave the world standardized structural steel, now has become the birthplace of standard precast concrete shapes, which simplify fire-proof construction and lower its cost through mass production.

Use of vibration, heat, and mass production methods are the three main features of the system of manufacturing Cemenstone, as the pre-cast material is known. Vibration while molding is said to produce a finer tex-

Above: Pouring the mix at one end of the continuous production Cemenatone mill. Right: A few of the pre-cast concrete shapes that can he produced with the same equipment

ture and a stronger product. Heat is used to hasten the chemical reaction of the coment when it is brought in contact with the other materials and water. It also is said to induce unform shrinkage and a product of a uniform light color. Mass production has been made possible by the development of a syrtem which permits rapid cycles of manifacture and the making of several shapes at one operation. The method of modifing curing, and aging produces elements with fultier cycles and corners so that they have the up-

Perance of cut stone
Among the products which can be pro-

Designed to speed up weeping of sidewalks and foors in industrial plants, the "Flying Duat Pan," invention of R. C. Howell, a Cleveland industrial engineer, is powered by a one-horsepower motor and mounted on General Streamline Jumbo Jr., pneumstic tires. It runs at a speed of about three miles as hour and can turn around in its own length. Picking up any type of dirt or debris, from fine duat to stones as the manipulated to work within an inch and a half of a factory will duced by this method are blocks for wall construction and channel-shaped, short-span alabs for floors and roofs, as well as longspan slabs, concrete plank, joists, brick, insulating tile, and veneering, also curbs, sidewalks, and fence posts.

The production equipment consists of a rigid steel frame over a curing chamber which produces a temperature of 160 degrees, Fahrenheit. A hopper, which fills the molds with concrete, maxed to a plastic state, rides on the top of the frame, together with withstors which agutate the mus. Steam from the curing trough keeps the molds constantly hot. After the concrete has hardened sufficient of the concrete has hardened sufficient to the concrete

ciently the products are lifted out in large groups and unloaded for aging under cover and in a constant temperature, to prevent inflavorable weather conditions from arresting the proper chemical reaction within the

COPPER CURES FUNGOUS

COPPER, passed through the skin by electric current, is being successfully used in treating fungons infections of the hands and feet by physicians at Yale University Medical School.

In the past, many remedica have been used to treat these painful and abhorrent akin infections without spectacular success. Of 37 patients treated at Yale by means of electric current, 26 have been discharged as cured. Some of them had severe infections of long duration, one for as long as 25 years. The average number of treatments given was

The afflicted person sits with his feet immerced in cannel pans and with the hands in other basins. When the infection is on the feet, the hands are immerced in all solution and the feet in 0.2 percent copper sultion and the feet in 0.2 percent copper sulting the solution. For infections of the hands the relations are reversed. The duration of the treatment is 20 minutes. Special apparatus has heen devised to obviate the danger of electric shock.

Dr. Howard W. Haggard, Dr. Maurice J. Strauss and Leon A. Greenberg described the new treatment in a preliminary report in the Journal of the American Medical Association.—Science Service.

RUBBER-TO-METAL CEMENT

There has long been need for a cement which will stick many different kinds of materials, including rubber, to metals. Such a cement has been developed by the St. Louis Rubber Cement Company and is available in all size packages from one ounce to 55 gallons. This product, which is celled Cripitic Cement, is easily applied, can be

made to be a quick or slow dryer, and to withstand any climatic conditions. The manufacturers claim that the longer it sets the more tenacious it is.

Griptite is made from a combination of rubber, selected gums, and chemicals. The result is a coment that "weldis" rubber to metal, anti-squeaks to metal, rubber to enmeded metal, felt to metal, blue wadding to inctal, cardboard to metal, and linoleium to netal and concrete.

TUBE-WALL-SCOPE AND MAGNAFLUX

TWO new procedures involving a recently developed instrument, the Tube-wall-cope, and a new application of the Magas-flux method are now being used to inspect, during production, both the interior and exterior surfaces of every length of J & L Blue Ribbon scanules set el integral joint drill pape manufactured by the Jones & Laughlin steel Copporation.

The Tubervalls-cope fills a long-fet need for an accurate, seventic method of impering the mode of military seventic method of impering the mode of inhibit goods for defecting the mode of tubular goods for defecting the mode of tubular goods for defecting the mode of the mode of tubular goods of the good of the mode of tubular goods of the good of tubular good of tubular good of tubular good of tremmer under under good of tremmer under under good of tremmer under good of tremmer tubular good of the good o

This test consists of placing the pipe in a magnetic field and then sprinkling the pipe with a metallic powder or solution. Even though not otherwise visible, any defect will immediately become apparent as the red powder is attracted by magnetic action to a flaw and collects there.

THE KORT NOZZLE

An appendage which is in-talled perma neuly on the stern of vessels to surround the propeller as a sort of table, and called the Kort mozde, is being rapidly adopted for use on small vessels. Thus device, which a handled in this country by the Draw depending the dependent of the propeller without in the country by the Draw which is handled for use on well-designed vessels and the first which is received by the propeller without in the property designed ones. In his no moving parts, no recurrence to moving parts, consumes an overlanding the property designed ones. The story of the property designed as the hill

The duty of the Kort nozzle is to control the direction and velocity of the water pass-

llow the Kort mozele drives a sylmdrical column of water sternward, thus obtaining a "productive push"

ing to, through, and away from the propt Ber, with the further dumy of obtaining additional forward thrust through the control of the socious value of the propeller "draw" on the hydrofioli sectuoued ring. The underlying principles through which this mozile game its superior propt flung efficiency are not induje technically are too long to explain in detail here. Generally speaking, the action of the propeller is to drive stermand a cylindric cal column of water and from this propeller is accompanied.

For coast-wise and harbor towing vessels an increase of tow rope pull lietween 20 per-

Left: The Tube-wall-scope in use Below: With the Magnaflux test, invisible pape defects are detected

The Kott nozzle installed on the Dutch motorship Joma. See text

cent and 35 percent may be expected at normal towing speeds. The case of the Motor-coaster Jome of Cronnigen, Holland, will serve as an example. Trails amade in calm water over a measured mile without the Kort mozile gave a speed of 7 88 knots with the engines developing 225 5 H P at 298 revolutions per minute while the Jome was consuming 89.4 pounds of fuel per hour. After the application of a Kort nozile, on the same course and under similar sea conditions, the vessel animated as speed of 68 knots with the engines developing 219 8 11P, at 322 rouss with the engines developing 219 8 11P, at 322 rouss with the engines developing 219 8 11P, at 322 rouss with the engines developing 219 8 11P, at 322 rouss with the engines developing 219 8 11P, at 322 rouss with the engines developing 219 8 11P, at 322 rouss with the engines developing 219 8 11P, at 322 rouss with the engines developing 219 8 11P, at 322 rouss with the engines developing 219 8 12P, at 322 rouss with the engines developing 219 8 12P, at 322 rouss with the engine of the engine and the second sec

A New Joint

A NEW district withing process success fully adopted in a number of industrial plants, provides rapid, nutomatic making of welds of lowestion and medium-cardious steels, standless and other alloy steels. The "Immuned" process uses as an electrode a lare welding rod automatically fed, heared by the passage of an electrice current from it to the work being welded. The end of the electrode is constantly covered by a special granulated material which is automatically laid down in advance along the sew in to be

The granulated material used is a highresistance conductor of electricity in the molten state, and hence makes possible the use of very high current densities which cause rapid generation of intense heat. It also acts as a licat invalidor and concen-

trates the beat in a small welding zone. The molten portion floats as a longind hindred over the weld metal, protecting it from the atmosphere, and the secual welding takesplace beneath this liquid blanket, without veldence of an arx, and without sparks, spatter, smoke, or flash. By using various spatter, smoke, or flash. By using various ordinations of imperage, whose, and welding spreed, the shape and the reinforcement of the weld can be varied and the depth of the basic may be to gulared as the property of the state of the D. Luttle, Inc.

NEW LIEF PRESERVER

Title belt worn by the bathing gut in our filtustration is the invention of G. J. Peterson of North Dakota, who spent almost four years in its perfection. It inflates and quickly becomes a life preserver in an emergency. The Swimaster, as it is called, has the appearance of a handsome swimming belt, uses ordinary Sparklet sphon certridges wathable at all drug stores, and

There is nothing unusual in the appearance of the swimming belt shown at upper right, but it can be instantly inflated to act as a life preserver, as pictured above

can be used over and over again. A slight squeeze of the helt buckle inflates the Swimaster to a hooyancy more than sufficient to float the heaviest person, even in hunting elothes, from 12 to 16 hours or more, in summing position?

Munters and fishermen may wear the licht under clothing where it will remain inconspicnous and still operate efficiently

PENNIES SAVED

HOLS-WIVES labut of inflanne, the bags in which sugar, from, rec, and other smilar materials are delivered to them, has at last stumidered his makers to action A new series of printing insks to be used to print labels on such bags gives supersions which are satisfactory so long as needed, that which can be readily swaded out by the housewife By using pignent inks with these removable ones, part of the design can be removable ones, part of the design can be well leave a stam in the doth when washed out with swap and water—D. H. and water to be such as the control of the state of the s

OLD MATHEMATICAL PUZZLE STILL INTRIGUES

O NE of the great mysteries in the history of mathematics is known as Fermat's last theorem. In the year 1637, brilliant Pierre Fermat, great French mathematician,

wrote in the margin of an algebra book this statement;

"If n is a number greater than two, there are no whole numbers, a, b, and e such that a" plus b" equals c". I have found a irrily wonderful proof which this margin is too small to contain"

Unfortunately, after Fermat's death to 1665, an examination of his papers showed that he never wrote out this "wonderful" proof And it so doing Fermat left a mystery

which probably every first rate mathematician since his time has puzzled over at least

Many of Fermat's mathematical followers spent enter lews on the problem and at least three large each prizes (one in 1907 amounting to nearly \$25,000) have been offered for a solution to Fermat's moment of inceptation. Like some modern move or eigenetic contest these prizes produced a vertiable current mathematicans, and all false proofs. The present status is that the theorem has been proved for values of a less than 617.

matical Society, Dr. J. Barkley Rosser of Cornell University described a method of treating a special, simplified form of Fermat's famous theorem so that many values of n can be handled at ouce. With this method he has proved this special case for all values of n less than 8,322,403.

This special form pais on the restriction that the number is must not divide a, b, or c. Previously Dickson, in 1998, had proved this case for numbers up to 7000 and, in 1925, Beeger did it for numbers up to 19000 By comparison Dr. Rosser's contribution is enormous—Science Sertife.

ILLUMINATION

"SIGHT is precious," says the Swashington Water Power Company, Spokane, "It is estimated we use our eyes for severe visual tasks about 30 percent more than was common a generation ago—and many times more than a century ago."

FOR HOMEBUILT RADIO FACSIMILE RECEIVERS

THE amateur who likes to build his own radio receivers can now add another interesting radio development to his accounplishments. He can secure the parts and build his own facomile radio printer Because of the great unterest amoned by thilatest development in radio, The Grosleyter parts mere you hould a Radio facomileprinter which the amateur can operate in connection with his own radio receiver.

Facumile radio printing is in its infanct today just as radio itself was 20 years ago, and with the possibility of radio printing cuming into widespread use in homes and in other places as yet untouched, the radio amateur has a highly interesting field in which to carry on his experiments.

Facsimile recorder which can be constructed from an available kit of parts

The Crosley Reado radio printer is a disvolument of the Firsh nethod (See Seintife American, June, 1938) and is being need in many places throughout the country. The time probably as not far distant when radio facionile printers will consumity delorer an interesting arrain of timely newterns and pictures of new events, as well asother information, into botuse and other ularer.

CONTROL FOR PEACH

ETHYLENG debloods, workle used in formating grain, his proved more of territor in controlling peach between the true in controlling peach between many materials, now used, and in addition at is casy to apply with little diager of in many to the tree and is relatively though the controlling peach from a superior of the controlling peach from a superior manufacture, and this emission is poured about the base of the tire of the tree of any agg and can be applied at any season. In It.

SEAR OFF STEEL SURFACE DEFECTS

P (ASII) No., searing flame is removing the totileneck in the otherwise high speed, or changed production of steel from the ore pile to the warehouse of the flamshed product. That bottleneck was the stage known as bloom funsioning, when the surface defects in the steel had to be removed to ment customer.

Flaming torches, burning oxygen and acrylein gas, are now searing of the outside surface of guant liftles in many sectualls of the land. They are replacing older methods which employed many men to chip off the defects with pneumatic chiests or linge machines—power-operated but mancontrolled—which did the same thing.

Flane scarling is the name of the now inthol The steel makes have been reluctant to talk much about it until it had nethroid a success over an appreciable period of time, in full scale commercial priodiction They had been foolied, too many times below, by other methods channed to have solved the problem of bloom husbing, are replacing skeptical howeve on the faces of the nation's sixed masters.

The Lin-De-Surfacer is the name of a flame scarfing device coming into increasingly wide use in steel plants. It takes its best position in the steel mill's otherwise continuous chain of production when it is placed in the blooming mill near the guant shears that cut off chunks of steel a foot in diameter and 10 or 12 feet load.

These chunks, the blooms, go through the flame-cutting treatment, lose their surface defects and pass on to the rolling nulls.

In actual operation the bloom passes into the unit and its aurface is pre-heated, to the point where it just begins to flow, in about two seconds. This is accomplished by multiple torch openings which may number as many as 28 orifices. Then, at the proper meatant, along comes oxygen gas and sears off the outer aurface to any depth desired up to a quarter of an inch.

In the de-surfacing unit the blooms move

WHERE SCIENCE ENDS HOSPITALITY BEGINS

The Waldorf, for example, is a magnificent scientific achievement, not only dependent on science when it was built, but continuously dependent on many sciences for the efficiency of its operation.

But every man of scientific turn of mind knows what we mean when we say that hospitality, in his own home no less than in the Waldorf, is something warm. Iwing and human that survives scientific detachment

And it is that ability to preserve the human touch, in spite of all our clockwork schedules and efficiency, that gives the Waldorf its unique reputation for manitaining close, cordial and communicable contacts with its patrons.

Besides, this year, when you come to New York, you'll get so much science at THE FAIR, that it'll be a genuine relief each day to return to the hospitality of The Waldorf-Astoria!

against the blast of oxygen flame at a rate which can be as high as 175 feet a minute. The oxygen velocity is low, in contrast to the high speed flame of the ordinary oxyacetylene cutting torch, and peels off the surface. The slag formed consists of about 80 percent iron and can be used over again to charge blast furnaces.-Copyright by Science Service.

PLASTICS

N 1926, production of plastics in the United States was 10,000,000 pounds. A fast jump to 30,000,000 pounds was made by 1932, and an enormous increase to 162,000,000 pounds in 1937.

CALOMEL, VALUABLE INSECTICIDE

DOSING cabbage maggets with calomel applied in a suspension around the appared in a suspension around the young plants, as a dust, or as a coating on the seed, has distinct advantages over most other methods yet devised for combating this troublesome pest, according to Dr. Hugh Glasgow, entomologist at the N. Y. State Experiment Station at Geneva.

The insecticidal properties of calomel were discovered largely by accident a number of years ago in some tests at the Station in which all of the salts of mercury were included as a matter of routine, explains Dr. Glasgow. Such striking control of the root maggot was obtained on the calomel plat, however, that it was immediately made the subject of careful tests, with the result that it was found to have some decided advantages over corrosive sublimate, the standard treatment, although no more effective than the latter in controlling cabbage maggot.

One of the chief advantages that calomel possesses is that there is little danger of injury to tender young plants from its use, whereas corrosive sublimate must be used in a fairly dilute solution and even then may cause injury to cauliflower and radish seedlings. Corrosive sublimate is also suspected of delaying the harvesting date of early cabhave and cauliflower. Because it can be used in heavier dosages, calomel generally does not need to be applied as often as corrosive sublimate.

Calomel may be applied in suspension in water, as in the case of corrosive sublimate, or it may be used as dust, or it may be applied directly to the seed at planting time. "In fact, any method that results in placing the calomel near the point where the eggs of the insect are normally deposited should re-sult in satisfactory control of the root maggot," says Dr. Glasgow.

TONETTE: NEWEST. SIMPLEST MUSICAL INSTRUMENT

ALL his life, Zeigner Swanson liked to tink-er with flutes, to play them and to build them. It is said that flutes are as old as willow branches and a tool to cut them; and "Zig" has amassed a collection of them showing their evolution from hellow willow twigs

QUANTITIES LIMITED-ACT QUICKLY

For sale by SCIENTIFIC AMERICAN, 24 West 40th Street, New York, N. Y.

One is a well-known product—methanol, or wood alcohol. Four others had not been previously discovered, although one of the group was described as theoretically possible by a German scientist. The properties of these new substances are such as to suggesther use as wood pre-cryatures, fungicides, insecticedes, adhesives, solvents, and plastic materials.

The co-discoverers, Dr. E. C. Sherrard and Dr. E. Harris, describe the first new substance as paraprophylyclolexanol, valuable as a solvent for organic gums and resins, and oils need in lacquir. It has value as a pie-creative, and its about as repellent to insects as creeoute.

The second and third substances, described as 4-propyl, 1, 2 dihydroxycy(oldex) and and 3 p hydroxycy(oldex) propanol, are thick liquids which become solid after standing a long white. Both may be made into plastic materials.

The fourth substance is crystalline and innamed, as the discoverers have not yet determined the positions of the carbon, hydrogen, and oxygen atoms of which it is composed.

Because of its complex chemical nature, ligam in its natural form has beliffed seen itself. By submitting it to the hydrogenation process, the Forest Service settinists changed its chimical nature so that it could be lanken down into component parts. The bydiogenation process already is in new comnercially in making hard fast from vegetanation grating phenomenal yields of gaodine and in getting phenomenal yields of gaodine and as good from natural perfording

In the laboratory twis the hydrogen atoms were added to a solution of puritivel lignum by means of livest and pressure and the use of a catalyst—copper chromoun oxide—another chemical indicating rapid reaction, yet taking no part in it. Under list treatment the dury, brown lignus solution changed to a links, streky, and colories fluid. The catalyst was removed by the use of a centrifuge, which winks on the principle of a certain september of the control of the contro

99.9999 PERCENT

PURITY of metals is difficult to achieve, yet very important in research, alloy making, metal conting. Metallurgists have made lead 99,9999 percent pure.

FOLDING, LIGHT-WEIGHT

O NE of the latest developments in the marme accessory field is a new lightweight anchor fabricated from high strength Monel sheet. It is welded throughout, except where the arms and stock meet the shank. These joints are pinned so that the anchor can be folded for stowing when not in user.

Made in a variety of sizes from six pounds to 47 pounds in weight, the anchor is so designed that the 11-pound size will hold a best 38 feet in length. With the conventional type of anchor, the general rule is to allow one to Iwo pounds in anchor weight for each foot of boat length. This lightness of weight

is made possible by the design of the anchor, combined with the inherent strength of Monel

Arms of the unit are set at right angles to the stock and are equipped with a set of sharp-pointed triangular flukes. These dig deeper and deeper as the pull of the craft is increased. The broad palms of the anchor, which will bury themselves completely in bottoms of clay or sand, provide an excep-

tionally strong grip. The auchor will not dig itself out of the bottom until a direct up-ward pull is exerted on the line. Then the sharp-pointed flukes readily cut then way out.

The light weight and small size of the anchor permit case of handling and reduce the danger of damage to the hull and topsides Monel is highly resistant to corresion and the anchor will not rust in fresh or salt water.

This anchor was designed and is manufactured by the Youngstown Welding & I ngineering Company -Inco.

RUBBER-LIKE SUBSTANCE FROM DAIRY BY-PRODUCTS

SCIENTISTS of the U S Bureau of Dairy making a transparent rubber-like substance from lactic acid of whey that has many promising uses in various industrial opera-

Known to chemists as polymethylacrylate, the water-white semi-solid material is closely related to the so-called organic glass made synthetically and used for highway reflectors. It is softer and more flexible than organic glass, however, but is very tough and clastic.

Laboratory results obtained by Lee T Smith and H. V Claborn, chemists in the Bureau's Division of Dairy Research Laboratories, indicate that polymethylacrylate can be produced as cheaply from lactic acid by their method as it is now produced from ethylene or alcohol by the cyanhydrin process. The Bureau scientists believe the cheapness of their process will contribute to the increased use of lactic acld.

Because of their unique properties, polyacrylates are already in demand for various purposes. Their transparency, elasticity, toughness, case of solubility, and stability to

sunlight and ultra-violet rays make them especially valuable in the preparation of lacquers, varnishes, inks, impregnating compounds, and cements.

All types of fabries, paper, and other fibrous materials may be coated or impregnated with the polyacrylates to make them resistant to water, oil, and gases Fabrics with these characteristics are useful in making ship's sails, balloon cloth, and clothing for protection against porsonous gases, Treated paper finds many uses, especially in the electrical industry.

Unlike the related organic glass material, polymethylacrylate alone is not suitable for making molded objects, either by the compression or injection method; but it can be combined with the organic glass to make a molding material superior to any of the original compounds.

RADIATION PYROMETER

NEW radiation pyrometer which uses A NEW radiation pyrometer unit, the Ardometer, shown in the illustration, is being offered by The Bristol Company.

This instrument measures the surface temperature of hot objects or masses above 1000 degrees, Fahrenheit, when the Ardometer unit is sighted so that it picks up the

heat rays emitted The temperature is recorded on a round- or strip-chart recorder or is indicated on a millivolimeter pyrometer

The Ardometer has this important feature, it can be sighted directly on the object in the furnace and in this position it measares instantly the temperature of the object itself It follows with fidelity the temperature changes in the material on which it is sighted

trons impinge on the plate, a green color shows. By changing the negative biasing voltage supplied to the grid, the stream of elecfrom to the plate can be varied from zero to the maximum of which the tube is capable. A pattern on the face of the plate shows the area normally bombarded by elec-

By placing a permanent magnet near the tube, the electron stream can be deflected by the magnetic field. The effect of the field on the electron stream can be seen plainly. This effect varies according to the way the magnet is applied to the tube.

The circuit used is similar to that in andio-amplifiers. A 60 cycle frequency is anplied to the grid and the tube output is connected to a loud speaker. The loudness of the audio signal corresponds to the area of the green glow on the plate of the tube.

SULFAPYRIDINE IN PNEU-MONIA CASES

ALMOST all deaths from pneumonia could now be prevented if pneumonia patients were given proper treatment on the first day they were taken sick, Dr. Perrin H. Long of Johns Hopkins School of Medicine recently told members of the American College of Physiciana. The millennium of no more pneumonia deaths, which probably could be achieved by the new chemical remedy, sulfapyridine, will probably never be reached, Dr Long said, because pneumonia patients do not see a doctor on the first day of sickness -- in fact, usually not until they are desperately sick.

Serum would not be necessary in the treatment of pneumonia, Dr. Long said, if

sulfapyridine could be given the patient the first day of his illness. From the standpoint of cost alone this would be a tremendous advantage. It costs about \$12 to treat a case of pneumoma by sulfapyridine but the cost of serum ireatment is at least \$75. Serum is not always available, whereas suffapyridine is both available and effective in all types of phenmonia -Science Service

RAILROADING'S LATEST CHAPTER

(Continued from page 361)

with a gear reduction unit. The furbing operates at a speed of 12,500 revolutions per munte and the diameter of the high pres sun totor is approximately 12 inches The gear reduction unit has a ratio of about 10 to 1 A main traction generator composed of two armatures mounted on a common shaft and in a common frame is connected to the turbine A three-phase alternator is mounted on the main generator shaft to supply alternating current used in the passenger car for lighting, air conditioning, and,

on some trains, part of the heating load A 50 gallon, self contained hotler of the water tube, forced circulation type and using distilled water, furnishes 45,000 pounds of steam per hour for the turbuse at 1500 pounds per square much pressure and at a temperature of 920 degrees, Fahrenben The steam is passed from a superheater through the high pressure turbine and then through the low pressure turbine. Then, justical of heing exhausted as it is on the reciprorating steam engine, it goes from the low pressure turbine to a condenser and is returned to the boiler in the form of water to be used over and over again. Only small quantities of distilled water are required to make up loss es No more than a few tankfuls would be required by the steam electric locomotive on a coast to-coast run. Compare this with the thirsty steam locomotive which may use as many as 200,000 gallons of water hauling a standard passenger train from Chicago to the Pacific Coast!

A 4000-gallon water tank of steel construction is installed in the nose of each cali of the steam-electric locomotive, this water being used for the most part in furnishing steam heat for the passenger cars

E LECTRIC energy from the turbuse gen-erators is feel to six traction motors of the axle-mounted type on each cah. Each of the motors has a nominal rating of 600 horse power. In addition to furnishing driving power for the locomotive, these traction motors have another important function. They provide electric braking essentially the same as that used for regenerative braking in the straight electric locomotive. This dynamic braking, as it is called, is used both for service stops and for controlling the speed of the train on long down-grades. On the steamelectric locomotive, it will hold the train on a 2.2 percent down-grade at any speed desired. without the application of any brake slives on either the locomotive or the train.

The motors become generators in the braking process and the power they generate is transmitted to a water-cooled resistor, a series of pipes through which water is forced to dissipate the heat generated during electric braking. The water leaves the resistor

as a mixture of water and steam, passes into the condensers, and is returned to the con-

A 3000-gallon tank for the two-eent-per gallon fuel oil is installed near the rear of each of the cabs, next to the condensers.

An ingenious control system maintains steam flow in proportion to the load on the turbine, as well as a constant steam pressure When the engineer moves the throttle shead, the control functions to increase the amount of fuel, water, and combustion air to the boiler, and the demand for more power from the generating plant is satisfied The process is simply reversed when the engineer decelerates the locomotive. The ratio of the fuel, combustion air, and water supplied is a fixed relationship, regardless of the main power demand.

An auxiliary turbine set drives a combustion air blower, feed water pump, and fuel oil pump through gear reduction units Getting the locomotive "steamed up" prepara tory to running is a simple matter compared with the process of getting the standard steam locomotive ready for service. A small vertical fire tube boiler with a capacity of 100 pounds of steam per hour is used Pro-pane gas serves as the fuel in this boiler If steam can be secured at a roundhouse or from some other external source, the main boiler can be started without the use of this auxiliary boiler.

The running gear of each unit of the steam-electric locomotive consists of two main driving truck frames, each carrying three driving axles. The two-axle guiding trucks proted to the main truck frames complete the running goar of a 2 C-C 2 wheel arrangement.

Crew space is up front, instead of at the rear of the unit as in the reciprocating steam locomotive, and from his comfortable chair the engineer can look out over the souls nose of the steam electric lucomotive and get a clear and unabstructed view of the track ahead A defrosting system and wip ers keep the windshield clean in sleet, snow, and rain storms. The engineer operates the locomotive by manipulating two controller handles and the usual air brake system, and as a final modern touch he even has a handset telephone handy at his elbow so that he can be in instant touch with other members

of the crew What effect this new steam-electric locomotive will have on the future of American railroading, only time can decide. Among already-known advantages, the steam-electric locomotive has a thermal efficiency from fuel to the driving wheels more than double that of the conventional locomotive Its ability to travel as far as 700 miles under favorable conditions without stops for fuel or water, plus inherent high rates of acceleration and braking due to high adhesive weight, are important factors in maintaining high speed schedules on long runs. There will be say ings in brake shoes and wheels for the entire train as well as for the locomotive as a result of the electric braking. Boiler trouble should be rare, due to the use of distilled water in a closed system which climinates corrosion and boiler scale.

It is certain that the performance of the new steam-electric locomotive over the historie line between Chicago and the west coast will be watched closely, for it represents the latest manifestation of that "breeding" of inhimited possibilities to which Hora-tio Allen referred 110 years ago.

CAMERA ADVENTURES IN WASHINGTON

THIS month we relinquish the chair to a guest conductor, no levs than Mrs (amera Angles, herself an enthiusastic fan, who describes the opportunities for picturemaking which she found on a recent visit to the Nation's Capital

Un like most natural capitals. Washington very dome ratis, photograph sally speaking Except for the Smithsonian Institute, where the picture possibilities are limited anyway, and the Senate and House agalerus, where they would be unlimited, not only are you permitted to carry your camera mit poblic buildings but the guards encourage you by pointing out interesting priture possibilities. This camera fan took pictures mostly of extensive of lindings in the amosphere of elevity and augulois trees can be taken from the windows of the Capital Capita

"Washington Sunset"

public buildings. From the top of the Washington Monument which towers over the city, you cam—if you can elbow your way successfully to the windows before other camera enthusiasts monopolize the best vantage points—get interesting bird's-eye-view whote of Washington.

Of all the buildings, the Lincoln Memorial lends itself best to picture taking because of its dominating position on the banks of the Potomac, and the wide spaces around it which permit the photographer to view it from every possible angle. Its majestic pillars cast striking shadows against the dazzing white walls. From the top stairs, frout, one gets as sweeping view of the Potomac; from the back, an interesting view of the reflecting pool extending from the Washington Monument to the Lincoln Memorial which, on a clear, windless day, mir rors both structures.

Other interesting picture possibilities are to be found in the Botanical Gardens, with its bewildering array of plants, flowers, trees, and so on, from all parts of the world, in tropical or other natural settings. You can

"Public Model"

stroll unmolested through the White House grounds (inside it is necessary to check caneras) but visitors are permitted to view only a few rooms. The White House lends itself to interesting alots both by day and by night, when it is bellikuluk illuminated.

when it is brilliantly illuminated.

If, however, you don't take to buildings,
exteriors or interiors, you can always wanlet down to the Tudal Basin—if you happen
to be in town during the cherry blossom
festival. The shot reproduced here was taken
on such a stroll when the sun was playing
hule and seek and the picture had to be
focused in advance and mapped the
moment the sun came out of hiding. You can
walk clear around the basin along a path
which hugs the water's edge for the view
from the water's edge does not intrigue you
sufficiently, you can hure a boat and try your

luck from the water

The Tidal Basin always attracts a good crowd and something interesting is bound to happen. The picture of "Daniel Boone" was taken the first day your photographer arrived in Washinston. "Daniel Boone."

spotting our camera, greeted us with a hearty smile and an even heartier offer to at a price. A little nonplussed, we corned his offer until a more charitable photographer of the male sex took him up on it. To express his appreciation, Daniel showed the young man, and an ever increasing throng which crowded around him, pictures which had been taken of Daniel in a Russian costume by a dentist photographer in the U. S. Navy. He also showed us pictures in which he appeared with Hedy

"At the Concert"

Lamarr in connection with one of her recent

Relenting, we accepted his offer but had considerable difficulty in getting him away from the crowds as well as inducing him to avoid posing. As his photographic income soared, he became even more loquacious. He is apparently a well known character and takes parts in historical pageants, fairs, and so on. Two young ladies from Philadelphia identified him as having ridden in a historic carriage during a celebration there. To us, Daniel confided boastingly that he expected to be at the World's Fair with Ford or some other exhibit. All the while, he never for a moment lost sight of prospective photographic victims. If an uncharitable photographer tried to shoot without paying, Daniel would pursue him, with the crowd after him, crying out that this was money he needed for food and lodging. When we finally parted, we gave him the address of Mr. Camera Angles in the event that he does turn up for the World's Fair.

Just before leaving the scene of this adventure, we could not resist taking a shot at the sunset on the waters which, though ordinarily like a mirror, had been made turbulent by a strong wind. Fortunately, we had remembered to bring a lens shade, for without it, this picture would not have been attempted.

On our last day in Washington, Marian Anderson was singing before a record crowd at the Lincoln Memorial. Because one of the guards had said he would be "shot" if we tried to slip under the ropes which held back the throngs, we had to content ourselves with leaning over the ropes and shooting from that vantage point.

The camera made many new friends for us. We found this time, as we had on so many previous occasions, that not the least of the

values of sightseeing with a camera are the exetting adventures to which picture taking invariably leads

CAMERAS AT THE WORLD'S

FAIR

WE have it on the word of the officials of the New York World's Fair that pho tography by amateurs will be freely permitted and, in fact, encouraged The only re strictions on this score are that professionals will be barred since the professional conces sion at the Fair has been awarded to Underwood & Underwood. Incidentally, the Eastman Kodak Company will do its own large bit by sponsoring photographic exhibitions by various organizations and by helping amateurs in their exposure and other photographic problems at the Fair. One of these helps will consist of specially built backgrounds against which the amateur may photograph his best girl, and vice versa

PRESS CARDS

THE notion seems to have gone abroad that a press card is something that may be purchased and automatically will admit the holder to all functions. The only press card of any value is one issued by the Police Department of the particular city in which pictures are to be made, and money will not buy 11. It is issued only to accredited working press photographers associated with specific newspapers. In New York City, the press cards are distributed by a central news reau, to which the cards are entrusted by the Police Department, and are issued for three months at a time

PRINT THROUGH THE BACK

F your negative looks too sharp for the picture's good, you may find the solution in projecting your negative through the back of the printing paper rather than by the normal procedure of directly onto the emulsion. The negative is reversed in the holder-that is, with the emulsion side facing the lamp rather than the lens—and the paper is turned upside down. If your easel has any metal or

other bright parts built into it, cover the easel with an ordinary sheet of paper and then place the printing paper, face down, on top of it Either single weight or double weight paper may be used, the double weight nation rally requiring a longer exposure than that needed for the single weight

NEW PHOTOGRAPHIC TERM

THE ever-widening use of exposure meters of all types has recently brought into sogue a brand new photographic term de scribing the act of using a meter to "read exposure The term is "expometering and is introduced by Joseph M. Bing, FRPS It seems that photography is destined to make its influence felt in the dictionary as well as the many helds at already touches

"DESIGN IN SUGAR CUBES"

TWO separate exposures of a simple setin mind than to give one a little more time than the other, provided the inspiration for the combination of the two negatives reproduced here Accidentally, one day, the two

Sturt of an inspiration ...

negatives being enclosed in the same glassine pocket, we looked at the negatives against a light and saw what we thought was an unfamiliar negative Actually, the two negatives were so positioned that they provided a strange pattern very much resembling a caricature of a human figure. So the two were placed in the cularger as they were, with the emulsion side of one facing the easel and the emulsion side of the other facing the light A rather long exposure was required,

... and what resulted

for one reason because two negative densities were being exposed, for another because of the overall density of the individual nega-tives. Had the job been done according to a pre-conceived plan, a darker background would have been employed in order to provide greater transparency, although in that case the shadow effects would have been less pronounced.

"KITTEN ON THE WINDOW SILL"

EVERY morning, some time before eleven, this white kitten sits on the window sill of the apartment just below ours, bathes itself in the sun and surveys the world below it. Our appearance at the window above at tracts her attention and she watches us through one of the window panes, partien larly attentively if we happen to have a camera in hand. One such morning, it occurred to us to expose a negative to this matutinal habit and the picture you see is the result

Kitten on the Window Sill'

In making the enlargement we hard up the edge of the wall with the long side of the print in order to overcome the tilt in the camera position necessitated by the subject The angle is, however, identified by the diagonal lines of the upper and lower parts of the window as well as the diagonal lines of

"Corridor Ceiling

LICHT"

THE opportunities for pictures that he even in humdrum subjects is illustrated by this shot of the interesting pattern sur-rounding a small ceiling light. Waiting for the elevator sometimes has its advantages, for it was on one such occasion that we happened to be studying the coiling-for lack of something better to do-and, noticing the practically symmetrical arrangement of the pattern "leaves" all around the lamp, thought of the camera hanging idly from the shoulder. It required a low, crouching position and a straining of the neck, the camera being of the range-finder type, to get into as central a position as possible under the circumstances, short of lying on the floor. At the full

HERE'S a miniature to take to the Fair, on a sea voyage, to the country or the shore-in fact, wherever the snapshooting's good.

Choosing any one of the three modestly priced models, you're equipped for splendid snapshots; Kodak 35's have fast lenses, precision shutters, up-to-date picturetaking features. You get up to three dozen little 35 mm, pictures on a single loading. (35 mm. pictures, you know, can be made into stunning enlargements.)

chromatic film, we made three shots, at 1/10, 1/25, and 1/50 of a second. Although we knew we could not fail to record the light, our chief concern was with the shadows which were projected upon a relatively dark ceiling. Also, because we were shooting directly into a light source, we expected flare

"Corridor Ceiling Light"

and were not sure just where this would strike the film. In one of them, luckily, the flare struck just outside the ring of shadows and we were able to make a print by excluding this flare spot through appropriate cropping. The square composition was inevitable because of the nature of the subject.

PHOTOGRAPHIC EUROPEAN Tour

THE picture train idea, started some time ago, has now risen to greater heights to assume the ambittous proportions of a First Annual Photographers' Grand Tour of Eu-Annual Photographers Grand Iour of Eu-rope. Organized by the Walker Travel Agen-cy, of Ridgewood, New Jersey, this first Eu-ropean photographic tour, by private motor coach, is to have as its photographic leader and mentor, the well-known pictorialist, Edward A. Alenius, F.R P.S., who will be the lecturer, advisor, and consultant on all phases of photography

The tour will begin on August 11 and will last through September 25, during which period the following countries will be visited: England, Holland, Belgium, Switzerland, Germany, Italy, and France.

ANNUAL LEICA EXHIBITION

THE annual assembly of the course of photographs made during the course of under way. Leica users are the year is now under way. Leica users are advised that no specific restrictions are placed on the choice of subject matter, which may be a portrait, an aerial, candid, action, medical, animal, insect, or any other type of picture. Actual color prints made from Leica color transparencies are also invited, as well as sequence pictures.

The rules announced for submitting prints to this, the Fifth Annual Leica Exhibition, are as follows: There is no limit placed on the number of prints that may be submitted; prints should not be less than 8 by 10 inches in size; prints may be submitted mounted or unmounted, but if mounted, the mounts should be of a light color and conform to the standard sizes; on the back of each print or

mount, the photographer should include his name and address; the lens used; shutter speed and disphragm opening; film used, developer for the film; filter, if any, as well as other accessories used to make the picture: and, if possible, the name of the paper ture; and, it possible, the name of the paper and the developer used to make the prints. Contact prints should accompany photographs but should not be pasted on the mounts; all packages should be addressed to E. Leitz, Inc., 720 Fifth Avenue, New York, N. X., and should hear the word EXHIBIT in the lower left corner.

SHOOTING IN THE BACK

OCCASIONALLY you run across a sub ject, such as a broomstick vendor, with brooms of various descriptions jutting out from under his arms and over his shoulders, which presents an opportunity for a shot in the back. These persons are usually on the go so it will be necessary to follow the subject and shoot as best you may. A good way to keep him in focus is to set your camera for a given distance, walk briskly or slowly, as the case may be, until you reach this distance between camera and subject and let the latter's walking speed pace your steps.
When the moment seems ripe, shoot quickly and use a relatively fast shutter speed as a precaution against camera unsteadiness at the moment of exposure.

Amateur Photographers

New Ways in Photocalarty, by Jamb Baschia, Eminently practical Jamb revery point of view, this new book contains nothing of theory and nothing that the advanced amateur photographer will not find valuable in one way or another. It covers the discussing such things as trick photography, photomurals, retouching, infra-red, and a number of other ambdivisions that will not be found elsewhere in as clear and conclea aman-

INFRA-RED PHOTOGRAPHY, by S. O. Rawlings. A treatise on the use of photographic plates and films sensitive to infra-red. Exposure and processing are fully covered; formulas are given for sensitizing, \$1.65.

UNIVERSAL PHOTO ALMANAC AND MARKET GUIDE. How, when and what to photograph in order to make money with your camera; where to sell different types of prints, \$1.00.

CAMERA LENSES, by Arthur W. Lockett. Explains simply and clearly, yet with scientific accuracy, all the underlying principles of lenses. \$1.10.

CHAMPLIN ON FINE GRAIN, by Harry Champlin. A complete hand-book on the entire subject of fine grain, including formulas and how to compound and nee them. \$1.90.

PHOTOGRAPHIC HINTS AND GADGETS, by Fraprie and Jordan. How to make all kinds of photographic accessories; from film claps to cameras to lighting equipment, and so on; 250 articles and nearly 500 illustrations. \$3.70.

ELEMENTARY PHOTOGRAPHY, by Neblette, Brchm, and Priest. You can learn much of the fundamentals of photography from this little book even though you have little or no knowledge of physics and chemistry. \$115.

PHOTOGRAPHIC ENLARGING, by Franklin I. Jordan, F. R. P. S. One of the most interesting and authentic books on enlarging. Its 224 pages coverevery phase of the subject and 75 illustrations, many of them salonwinners, show the value of correct technique. \$3.70.

PORTRAIT PHOTOGRAPHY, by H. Williams. Fundamental principles of composition and lighting, paving the way to satisfactory results in this particular branch of photography. 84.45.

SCIENTIFIC AMERICAN

24 West 40th Street New York City

JACOB DESCHIN, conductor of our "Camera Angles" department, will answer in three columns questions of general interest to anadeus photographers. If an answer is descret by mad, ecclose a stamped, addressed medical conversation for the special of the production cannot understand the production of the production of the production of advanced to nursely and columns of the production. The Advanced of the survey of the surv

Q. Occasionally, in exhibition prints, I notice a fine lustre which appears to be a surface treatment. Can you tell me how this is done?—C. L.

A. Mix equal parts of olive oil and turpentine and apply evenly over the surface with a wad of coliton, following this by poltching with a soft cloth. Another popular formula includes.

Pour a little of the solution on the print and then rub in with cotton. When the entire print has been treated in this way, polish dry with a soft cloth or a fresh pad of dry cotton

Q. Not being too familiar with the various makes of photographic lenves, I am at a loss in making a selection. I am at a loss in making a selection. I am to the property of a winders 21½ by 2½ reflex type camera. Which would be the more desirable, one equipped with a Rodenateck Trinar to 1/300th or one having a Heliar //3.5 lenv in a Compur Rapid shutter, I second to 1/300th ~ J. K. 1 second

A. For all practical purposes, one lens will give a good a performance as the other Your choice, therefore, must be on the abase of the other factors involved, the higher lens speed of the f/20 over the f/35, which is negligible, and the difference in the top shutter speeds. It would seem that the choice would depend cheefy on the design of the camera. Basically, they are the same, of course, but there are other factors which, in a personal estimate, would place one camera above the other.

Q. Can you cite me references to information on the hypersensitization of film by mercury vapor? Also on the subject of photography by Infra-red light? —J. A. M.

A. The method of dry hypersensitizing with mercury vapor is fully described by the discoverers, Dr. F. Dersch and Dr. H. Luerr, of the Agía Ansco Research Laboratories, in the report of their experiments printed in the Journal of the Society of Motion Picspie Englishers (Vol. XXVIII, No. 2).

We believe that you may be able to obtain a reprint of this report by writing to the Agfa Ansoc Sompany at Binghamton, Newberling to the Agfa Ansoc Sompany at Binghamton, Newberling to the Agrant of
Q. At what aperture does my //2.8 lens reach its maximum resolving power?—D. G. L.

A Generally, this occurs at the stop [7:56], that is, is, to stops smaller than the maximum specture of your lens. For this reason, if perfect sharpness is what you want, you would do hest to try to work at this apertitum whenever possible Of source, shopping down will give you greater depth of field, in which case you will be willing to secretice the self-section of the state of the section o

Q. Is there any means of achieving an //64 aperture on my three-inch lens by means of a sort of Waterhouse stop?

—A. I. W.

A. The stop / 22 as the smallest that has been found practical with lenses of this short local length, but the great depth of these miniature lenses as compared with those on the larger cameras more than makes up for this lamination as to disphragm stops. The reason that extremely small always used as //54, cannot be obtained with the miniature daphragmas in at the diffraction of light at these small operatings would be too great and the standard of the second control
Q. My camera case has been used so long that it could at and a little reconditioning. What is a good polisher for this purpose?—D. K.

A. Propert's Saddle Soap is a standby with many. An excellent formula that you can make up yourself and rub into the leather with a soft rag consists of 50 parts lanolin, 40 parts castor oil, and 5 parts each of sodium steraste and japan wax.

Here is the fatest streamlined adultion to the popular in or of boilins. So me ministures I in remarkably likelt and compact, yet by a perision instrument in extra waves of the world Among the many featurest is a bulli-in transpe inder—knows in turnile and optically perfect—operating on the split-insage principle. BURLEIGH BROOKS

TELESCOPTICS

A Monthly Department for the Amateur Telescope Maker Conducted by ALBERT G. INGALLS

TO Nature (London), in which scientists regularly report progress in their work for the information of other professional scientists, Dr. Walter S. Adams, Director of the Mt. Wilson Observatory, has given the account of work preliminary to final figuring of the 200" mirror which follows.

The present figure of the 200" mirror approximates closely that of a sphere with a radius of curvature of 111 feet. The disk was first shaped on front, back, and edges by grinding with coarse Carborundum and the center was then hollowed out to a depth of about 3%," with the aid, first of a 50" tool, and then of successively larger tools up to the full size of 200". As the spherical figure was approached, finer grades of Carborundum were used, so that when optical tests became necessary only a few hours of polishing were needed to give the surface sufficient reflecting power. During the first stages of work upon the disk, the cylindrical holes on the back of the mirror and the large areas between the supporting ribs were filled with plaster of Paris, and after the face and back had been made parallel the 40" opening at the center of the disk was closed with a glass plug weighing about one ton. The plaster of Paris was removed when the surface had reached nearly the required form, and the mirror was placed upon rubber pads which rest on the frame of the support system of multiple counterweighted levers. The friction of these pads was required to neutralize the strong lateral pull of the grinding and polishing tools making contact over so large a surface, and for this reason the horizontal plates of the supporting system were not engaged. The optical tests, however, were made with the mirror vertical and balanced upon the support system just as it will be wh in use on the telescope. Future optical work, including the parabolizing, will be carried on with the intrror resting upon the rubber pads; but these will be removed when the

figuring is completed
"From the first the optical tests of the
mirror proved to be most satisfactory No

change was seen in the figure when the mirror was tipped repeatedly from a horizontal to a vertical position or when it was rotated. Also no local deformations could be detected at the points of contact of the 36 individual lever supports. In fact, the support system was found to be performing quite as well as had been boped by its designers. The length of the radius of curvature proved to be about 2" less than had originally been planned, but this slight difference, amounting to about I" in the focal length, is far within the limits allowed for in the design of the telescope, and it is probable that no attempt will be made to reduce the amount through polishing. The surface was found to be reasonably free from zones, hut a small amount of astigmatism was preent amounting to about 0.1" in the optical cut-off at the center of curvature. This proved to be due to a slight deformation of the disk caused by the horizontal pads upon which the mirror rests. [Supplementary note added in letter from Dr. Adams to Scientific American, to bring article up to a later date: "Through suitable changes in the supporting pads this astigmatism has now (March 15) been eliminated by a small amount of fine grinding and polishing. The zones have also been considerably reduced and the entire mirror surface is nearing an accurate spherical figure. Work will soon be commenced upon the final figuring of the 120" plane mirror to be used in testing the parabolization of the 200" surface."]

"Although the final parabolic curve of the surface of the mirror will be only 0.055" deeper than the spheroal curve, the area is o great and the process of polishing so slow that it is planned to make most of the change through fine grinding and to leave but the final stages of the figuring to the polishing tool. This procedure has already been found successful in figuring the spherocal curve.

"Accurate tests of the parabolic figure of the 200" mirror will require the use, as an auxiliary plane, of the 120" mirror. The com-

pletion of this mirror will be one of the next major undertakings in the optical shop. It is at present shaped on front, back, and edges, and the surface has been ground approximately flat. It is planned to figure the three auxiliary hyperbolic mirrors, one for the Cassegramian and two for the coudé com-bination, by the method devised by Hindle, without the use of the 200" mirror, Four spherical mirrors, each about 40" in diameter and with a radius of curvature of 25', are being prepared for this purpose, two being very nearly completed. The mirrors will be used side by side in a cloverleaf pattern and provided with adjustments for bringing their centers of curvature into accurate coincidence.

A few figures are of interest as inducating the scale of the optical work on the 200° mirror. About five tons of glave have been removed in the process of slaping and figuring, and about 20 tons of Carbornadium laws been used for grading. During the polyshing, about 50 pounds of rouge as hour is the warage consumption with the full said tool, and but a small fraction of this material can be salvaged. As a result, rouge has been purchased in quantities hitherto quite under the purchased the purchased in quantities hitherto quite under the purchased the purc

F you can train your eyes to perform sunably, you can superpose the two images shown in Figure 1 and obtain a three-dimensonal view of the 200° mirror and of the lettered image. You are standing in the lolly stuster's gallery in the Opical Shop at the California Institute of Technology, in Pausciae, California Institute of Technology, in Pausroux, California, looking through the winches, California, looking through the wineless, California, Indiana, and the contraction of the control of the conputer view of the company of the control of the

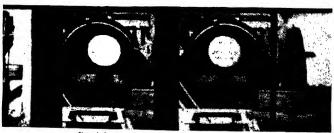

Figure 1: Stereoscopic views of the 200" telescope and reflected image

approximate eye level and 2' or so in front of the window. In Russell Porter's words, "you'd swear the image was material. Startling!" It seems to hang in space and you feel the urge to feel of it, others comment.

Thus far, however, there is nothing stereoscopic about it; in fact, the stereoscopic part has no connection with the apparatus or mirror but was obtained by taking two pholographs from the visitor's gallery, the second one made with the camera shifted sidewise about the same distance as the separation of the average man's eyes. These photographs were taken by David O. Woodbury, an amateur telescope maker who, after spending several months in Pasadena and Mi Palomar, has written a book about the 200" telescope, one chapter of which was recently pre-published as an article in Reader's Di-(the entire book is due to appear in October)

There are three ways to get the threedimensional effect (1) use a mounted pair of primanic lenses; (2) hold a long strp of cardboard between the end of your nose and the center of the pair of pictures, so that the right eye sees the right-hand picture alone and the left eye the left-hand picture alone, and then try to drift off into a focus on infairly think dreamily about that brunettel, or (3) command your eyes to do the Irick without any cardboard—this can

he done hy many, after a bit of practice.

The square object in the immediate fore-ground is a rack to carry the kinte-edge, when the purpor is tested à le Foucault.

THE BEGINNER'S CORNER

ROSPECTIVE beginners at telescope making very frequently have attacks of deep-dved doubt regarding their ability to make a telescope, and to these we commend the two photographs reproduced here, showing telescopes made respectively by an 11year-old lad and a lady. Not that telescope making is a juvenile or feminine hobbyin most cases it pretty definitely isn't. Simply, these telescope makers are beyond average in ability, for age and sex, but not men. Donald Bird is the youth and Wallace (

Donald Bird and his telescope

Swank science teacher at the Eaton Rapuls Public Schools, Eaton Rapids, Mich, sends us up account of his success, stating that Donald was 11 years old when he finished this telescope Some of your readers may think," he continues, "that Donald did perhaps a little of the work and an older person most of it, but such is not the case, he did it all His mirror is 414" in diameter with focal length 34", and is mounted in an octagenal tube of plywood He used pipe fittings for the mounting" to far as the conductor of this department can recall. Donald Bird is the youngest lad to have made so creditable a telescope. Natural mechanic.

The lady in the other photograph is Mrs. Albert M. Bonelli, 2515 Drummond St., Vicksburg, Miss, and she states that "the

Mis. Bonelli and her reflector

in Scientific American that it wasn't impossible for me to do what others had done, and that I might realize a life's ambition liv making and owning a telescope 50 I obtained a kit of materials, your instruction book 'Amateur Telescope Making,' and got husy This 6" reflector was the outcome, after 72 total hours of hard work

In difficulty the amateur telescoptical hobhy starts at the level of work such as these examples and may be made to extend just as far as the follower cares to extend it toword and into really advanced work

ROM a very old hand at the telescope making hobby, Harold A lower, of San Diego, we receive the following comment: "Here is something I think you ought to bear down on, in your Beginner's Corner—the chapter in 'Amateur Telescope Making' on roual testing. I have found that there are a surprising number of amateurs, some of whom have made several mirrors, who don't even know that chapter is in the book. Lots of them think all they need to do is use a Ronchi grating, and polish until they get curved lines. Naturally, the result is usually a deep hyperbola. Honestly, I think there would be more good mirrors if the Ronchi test had never been heard of. It is useful, of course, but most beginners depend on it too much

The chapter on zonal testing extends from page 96 to page 100 of "ATM".

TELESCOPTICS

(Continued from preceding page)

inclusive, and a convention of amateur a tronomers will be held on August 19 and 20 tronomers will be near on August 17 and a Lin "Amateur Telescope Making "Advanced," the sequel book to "Amateur Telescope Making," H. E. Dall describes the camera obscura, which is essentially a refracting telescope for use from indoors. The first since then to make one is William R. Crosby, 566 Glide St., Rochester, N. Y., a member of the thriving group of amateurs in that city Figures 2, 3 and 4 show the design and construction. At the top, in Figure 2, is an elevation showing a roof and, pro jecting above it, a flat both prvoted and rotatable. This picks up rays from any chosen object and directs them downward through the objective lens shown, which projects an image on a horizontal viewing table several feet beneath. Here the image may be viewed with the eye or, if still higher magnification is desired, with a microscope called a viewing telescope. The lower elevation shows the apparatus from another quarter.

Crosby, however, did not build his camera obscura into his house but into his autom bile trailer. Figure 2, taken outside, shows the trailer roof and the raised flat, while Fig-

Figure 2: Roof, flat, and its hat

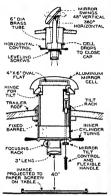

Figure 3: Front and side views

Figure 4: The inside end of it

ure 4 shows the interior part of the instru-ment, also the interior of the trailer (this Crosby also built).

Your scribe has sat in this trailer, rotated the flat and examined the landscape roundabout, and can testify that the spectacle came far above best expectations. Because the observer sits in the dark, his eye is not skyflooded. Therefore the large image on the table appears to be vividly colored—even more vividly than the actual landscape. A long, continuous panorama of greens and sky-blues aweeps across the viewing table, which in this case is the dining table of the which in this case is the dining table of the trailer, and several persons can examine it at one time. For astronomical work the cam-era obscura equates with a refractor of the enclosed observing room type.

CURRENT BULLETIN BRIFT'S

(The Editor will appreciate it if you will mention Scientific American when writing for any of the publications listed below)

15 YEARS BURNETHI BRUSH IS a 30-page pamphlet which deals specifically with the use of aluminani paint for wood prim ing A number of excellent photographs show the results obtained with this protective coat ng both from the standpoint of preserva tion of the wood as well as of the dinability of the paint which is applied over the pri mer Aluminium Company of America, Pittsburgh, Penusylvania -Gratis

HALF A MILLION MEN IS a 16 page booklet designed to picture what manner of man is the steel worker, not only from the economic side but from the human and social side as well. The illustrations combined with poctorial graphs give an excellent insight into this large group of American industrial cuiployees American Iron and Steel Institute, 350 Fifth Avenue, New York, New York -Grans

SPEED FLASH BOOKIET IS an illustrated 36page manual on Speed Flash Photograidiy li includes examples of prize winning pictures, complete exposure charts for distance and various size flashbulbs, including both foil and wore types, and exposure recommendations for all films. Drawings provide lints on how the Speed Flash owner may make adjustments for various condi-tions and different types of bulbs. The Kalart Company, 915 Broudway, New York, New Vorl. -Cratis

PRIVATE INTEREST AND PUBLIC RESPONSIBILI-TY, by Edward L Bernays, reflects the attitude of a counsel on public relations to ward our present system of conducting in-dustry and business. He deals with such things as the basis of democracy, the free competitive system; the importance of progress through change, scientific inquiry, the need of business for objectivity; and self-regulation of industry Edward L Bernays, 420 Lexington Avenue, New York, New Varl Cratis

CHENRY FLASHING IS a 16 page booklet explaining the principle of cutting off seenage and leaks through masonry walls exposed to rain by means of copper flashing extending through the wall as a positive cm-off Revere Capper and Brass, Inc., 230 Park Ave., New York, New York - Gratis.

ENIARCING, THE REAL FUN OF PHOTOGRAPHY is an eight-page booklet that gives the fundamentals of projection printing for the amateur It contains a series of excellent photographs that illustrate various steps discussed in the text Federal Stamping & Engneering Corp., 25 Lnjnyette Street, Braok. Iyn, New York. Gratis.

ALLIED'S RADIO BIJLDER'S HANDBOOK IS & 30 page booklet prepared to assist radio beginners to get started in building radio receiving sets. The essential fundamentals

are explained in detail and many circultare given, together with data for simplified construction. Illustrated throughout with clear and comprehensive drawings and a few photographs, Allied Radio Corporation, 833 West Juckson Blvd., Chicago, Illinois.-10 cents.

REPAIR CLAMPS AND SADDLES FOR SILES AND CAST IRON PIPE, Catalog No. 384. is of particular interest to those who are concerned with the maintenance of pipe lines of any type. These repair devices are available for use on lines carrying steam, hot or cold water, gas, oil, ammonia, or hrine A number of types adapted to various applications are illustrated and enough in formation is given to show their particular uses M B Shinner Company, South Bend, Indiana - Gratis

ELECTRICITY AND WHELLS, by Ralph A. Rich ardson, is a 32 page, fully illustrated booklet that tells in an interesting manner of electrical more as from the discovery of the magnet down to the present day It re views in particular the part played by electricity and electrical devices in the modero motor car General Motory Cornaration, Broadway at 57th Street, New York, New Yarl. -- Gratis

MICA THANSMITTING CAPACITORS of a new highly efficient design are completely de cribed in a pamphlet now available. The diagu of these capacitors is such as safely to chiminate corona and to reduce internal hear ing Dielectric loss in this muits is remarkably low, permitting long periods of heavy-duty operation. Catalogue No. 161. Cornell-Dubilier Fleetrie Corporation, South Plain field, New Jerses -- Gratis

GET THE INSIDE SLOWY IS AN Attractive and interestingly written looklet that describes one particular type of household re frigerator and shows the many advantages which are claimed for it by its manufacturer The pamphlet also goes into some detail regarding the construction and testing of these refrigerators before they reach the ultimate consumer. Technicalities are dealt with, but in simple, understandalde language General Electric Company, Nela Purk, Cleveland, Obio -Grntis

JACKSON EYESHIELDS IS a folded circular which illustrates and describes various types of eyeshields which have been designed specifically for the protection of industrial workers Jackson Electrade Halder Co. workers Jackson Electrade Haiaer Co 15/22 Mach Avenue, Detrait, Michigan --

THE PICTURE STORY OF STREET, is a 48-page lavishly illustrated booklet that tells the whole story of its subject from the mining of the are through smelting, fabrication, and testing, to the finished steel and its uses in the home, in transportation, in construction, and in industry. American Iron and Steel In stitute, 350 Fifth Avenue, New York, New Varl _Cratis

VICTOR PROTOGRAPHIC SPECIALITIES IS A 16page catalogue that deals with a wide range of lighting equipment for the amateur photographer as well as the professional. James H. Smith & Sans Corp., Lake and Colfax Streets, Griffith, Indiana.—Gratis.

LEGAL HIGH-LIGHTS

Patent, Trade Mark, and Related Legal Proceedings That May Have a Direct Effect on Your Business

By ORSON D. MUNN, Litt.B., LL.B., Sc.D.

New York Bar Editor, Scientific American

FAIR NEWS

THE New York World's Fair Corporation has recently restrained a publisher from using the title "Illustrated Fair News' in connection with a magazine relating to the New York World's Fair. The publisher originally published a magazine entitled "World's Fair News" and the New York World's Fair Corporation obtained an in junction restraining him from publishing a magazine under that name. Shortly after the original injunction was issued, the defendant indicated his intention of using the name "Illustrated Fair News" in conthe magazine and the New York World's Fair Corporation made an application to have its injunction extended so as to restrain the new name. The Court extended the injunction and restrained the use of the new name on the grounds that the publication "was ob yously designed for the purpose of enabling them to continue their exploitation for business purposes of the possibilities arising out of the World's Fair

EXPERIMENTATION

PATENT for a process must fully de-A serihe the process so that it can be carried out by the proverbial "man skilled in the art" without the necessity of any further experimentation, If further experimen tation is necessary to carry out the process. the patent is invalid for the reason that it is indefinite and does not fully disclose the invention

This principle is exemplified by a recent suit for patent infringement which involved a patent for a process for propagating yeas in which the production of alcohol is reduced to a minimum. In describing the process the patent suggests that seed yeast be placed in a wort having a specific gravity of one degree Balling After the process of reproduction is initiated, concentrated wort having a specific gravity of approximately 12 degrees Balling is slowly and substantially continuously added to the original wort over a protracted period of time. The patent states that the concentrated wort should be added "at a rate such that not only the alcohol which may have been formed from the quantity of sugar present in the diluted portion of the wort, but also any alcohol which may be formed from the sugar which is present in the added wort, can be assimilated imme-

diately by the yeast." The Court held that further experimentation was necessary in order to ascertain the times and manner in which the concentrated wort should be added. For this reason the Court held that the patent was indefinite, did not fully disclose the invention, and accordingly was invalid. In reaching this conclusion the Court made the following

"But even if the process disclosed by Hayduck be held to constitute invention, the patent is invalid for indefiniteness as was held by the learned District Judge Both the times and manuer in which the concentrated nutrient solution is to be added may be ascertained, as we have stated, solely by ex perimentation. The disclosure of the patent is therefore too vague and indefinite to con stitute invention "

DOUBT

IT is an established principle of patent law that in connection with the prosecunon of patent applications all doubts with regard to the question of invention must be solved in favor of the applicant Thus in a case where doubt existed as to whether the advance made by the applicant for a patent rose to the dignity of invention or merely amounted to mechanical skill, the doubt should be resolved in favor of the applicant and accordingly a patent should be

In a recent case involving an application for a patent on a method of making artificial sausage casings the Examiner had originally held that two of the claims were patentable Thereafter the Examiner reversed his decision and held that the claims in question were not patentable. On appeal to the Court of Customs and Patent Appeals it was con tended by the applicant that the Examiner's action in originally allowing the claims, and then rejecting them, indicated that there was some doubt on the question of invention It was argued that in accordance with th principle set forth above the doubt should he resolved in favor of the applicant and the claims should be allowed. The Court of Customs and Patent Appeals rejected this contention and held that the merc fact that the Examiner had reversed himself did not indicate that there was doubt on the ques tion of invention.

BREATHING

THE word "breathing" as applied to tex tile fabrics was held to be descriptive by the Court of Customs and Patent Appeals and accordingly not registerable under the Federal Trade Mark Act of 1905.

A textile manufacturer attempted to regster the words "Breatling Back" as a trade mark for pile fahries having an adhesive coating on the back thereof which was impervious to water but pervious to gases and air. The registration of the mark was opposed by a competitor of the manufacturer on the grounds that the words "Breathing Back" were merely descriptive of the characteristics of the pile fabric. The Court found that the word "breathing" had been used for many years to describe artificial leather and certain fabrics which were perreasing and certain tables which were per-tions to gases and air. It was accordingly concluded by the Court that the words "Breathing Back" were merely descriptive of the pervious characteristic of the pile fabric and under the circumstances the words could not be registered as a trade mark. In rendering its opinion the Court stated as follows:

"We are of the opinion that 'Breathing Back' as applied to applicant's goods does nothing more than to describe the character of the back of applicant's pile fabric which, by reason of its porosity, permits breathing or passage of the air through the back."

ANTENNA

IN a recent case of importance to the radio eommunications andustry the United States Supreme Court held that a patent on a directional antenna was not infringed hy autennas employed by one of the large 1adio communications companies

The Court found that the patent in suit related to a V-shaped wire antenna based on the so-ealled "Abraham formula," which provides that when radio activity is projected from a charged wire having a length which is a multiple of one half the length of the waves projected by the antenna, the angle of the principal radio activity is a function of two variables, namely, the wavelength and the number of half wavelengths contained in the wire. The patent in suit set forth an empirical formula based on the "Abraham formula" for determining the most efficient angle for disposing the wires in a V-shaped directional radio antenna. The Court found that the patent, being based on the "Abraham formula," was strictly limited to an antenna in which the length of the wire was a multiple of onehalf wavelengths. All of the antennas employed by the defendant, with the exception of one, were found to have a length which was a multiple of one-quarter wavelengths but not of one-half wavelengths. These antonnas were held not to come within the "Abraham formula" and not to infringe the patent.

The remaining autenna which had a length which was a multiple of one-half wavelengths was found to be disposed at an angle smaller than that prescribed by the formula set forth in the patent in suit and it was held not to he an infringement

SPACHETTI

MANY spaghetti caters will no doubt be annoyed by allegations of the Federal Trade Commission that the authenneity of spagheth is not determined by the length thereof. In a recent proceedings insututed by the Federal Trade Commission against a manufacturer of spaghetti and macaroni it was charged that the manufacturer was guilty of unfair methods of competition because his advertising matter stated that macaroni and spaghetii not made in long lengths was not genuine. The Commission charged that these statements were false, deceptive, and misleading and the manufacturer was ordered to show cause why he should not cease and desist from making further representations of this character,

Are You-

putling your spare time to good advantage?

one of the many who are seeking a new field to en-

weeking a means to save mones wherever possible?

If you are, here is a practical solution to your problem.

HOPKINS' CYCLOPEDIA OF

FORMULAS

Is the foundation for the beginning of a fascinating hobby; the groundwork on which to build a practical knowledge of useful chemical facts.

Is the foundation for hundreds of suggestions for those who are seeking salable articles which can be manufactured at home profitably on a small scale.

IF you want to save money on wines and liquors; your dyes, inks, polishes, soaps, paints and varnishes. adhesives, antiseptics, bleaches, cosmetics, etc.

You can profitably make them from the 15000 formulas contained in the 1077 pages of

HOPKINS'

Cyclopedia of Formulas \$5.50 postpuid (domestic) For sale by

For MEN

who want to become independent in the NEXT TEN YEARS

IN the Spring of 1949 two business men will be sitting in a mid-town restaurant. "I wonder what's going to happen next year," one of them will say. "My business is fine now—but the next few years are going to be hard ones, and we may as well face the facts."

The man across the table will laugh.

"That's just what they said back in 1939," he will answer. "Remember? People were looking ahead apprehensively—and see what happened! Since then there habeen the greatest growth in our history—more business done, more fortunes made, than ever before. They've certainly been good years for me."

He will lean back in his chair with the easy confidence and poise that are the hall-mark of real prosperity.

The older man will sit quiet a moment and then in a tone of infinite pathos:

"I wish I had those ten years back," he will say.

• Today the interview quoted above is pinely imagmay. But be assured of this—it will come true. Right now, at this very hour, the bisiness men of America are dividing themselves into two groups, represented by the two individuals whose words are quoted. A few years from now there will be ten thousand such luncheons and one of the men will say

"Twe got what I wanted."

And the other will answer.

"I wish I had those years back."
In which class are you putting yourself? The real difference between the two classes is this—one class of men hope vaguely to be independent concetme, the other class have convinced themselves

CONTRIBUTORS TO THE COURSE

Just a few of the business leaders who have contributed to the Institute training course are such prominent men as

Ldward R Stettinius, Jr. Thomas J Watson Chenman of the Board U S. Steel Corp Business Mach Corp

Alfred P Sloan, Jr Chairman of the Board General Motors Corp Major B. Foster Chairman, Dept of Banking and Pinance N. Y. U.

de Nemoors & Co , Inc Colby M Chester, Jr Chairman of the Boan General Foods Corp

Prederick W. Pickard Vice-President E I du Pont

"PORGING AHEAD IN BUSINESS" Is an interesting, helpful looklet. It is yours for the asking Send for it. Measure yourself by it I olso clearly, for a few moments, into your next few years. Whether or not you will follow the path it points is a matter that you alone must delow

that they can do it within the next few years. Do you believe this? Do you care enough about independence to give in a chance to prove it? Will you invest one single evening in reading a booklet that has put 400,000 men on the road to more raily progress?

This booklet costs you nothing-and for a good reason. It is worth only what you make it worth. It explains how

for more than thirty years it has been the privilege of the Alexander Hamilton Institute to help men shorten the path to success; to increase their earning power, to make them masters of the larger opportunities in business.

Why Tomorrow Will Be Better Than Today

BETTER houses... better factories better roads and food and clothing. Because with pencil and graph, with slide rule and calculation, the engineer is charting the way is turning visions into realities. He is applying the findings of science to the task of satisfying your needs and wants

Under his hand there takes shape the steel mill or textile mill of the future. Automobiles and overcoats, made by improved methods, will be better, yet less expensive More efficient turbine-generators—and cheaper electric power will lighten the tasks in every home Improved shoe ma-

chinery and better and less expensive pairs of shoes

The engineer's application of electricity to every branch of industry has helped to make America the greatest industrial nation in the world—has helped to provide you with the highest standard of living the world has ever known. And General Electric engineers and research scientists, working in partnership, have led in this electrical progress G-E research has provided new knowledge; G-E engineers have put shat knowledge to work to make available more goods for more people—at less cost.

G-E research and engineering have saved the public from ten to one hundred dollars
for every dollar they have earned for General Electric

CARL SANDBURG

IN A RECITAL OF AUTHENTIC
AMERICAN FOLKSONGS FROM HIS COLLECTION

"THE AMERICAN SONGBAG"

Gallows Song ("Sam Hall") I Ride an Old Paint Foggy, Foggy Dew The Horse Named Bill

Woven Spirituals
The Good Boy
Mama Have You Heard the News?

I'm Sad and I'm Lonely

(Eight Songs on Four 10" Records)

"Never, in our recollection, has the personality of a man come through the mechanism of the phonograph so startlingly true to life as has Sandburg's.

"The vast audience who have heard Carl Sandburg sing these songs at intimate rectrals in the colleges and clubs of this country, the students who have studed his poetry, the numberless owners of copies of 'The American Songbag' know how personal is his art. For those who have never heard these songs as Carl Sandburg performs them, we can but list the titles and advise that, no matter how familiar the individual song, you will agree that you have never heard the depths of tolk mins, sounded intil you have heard them sung by Carl Sandburg "— Musscraft

"Carl Sandburg, famed as a poet, would rather be known as the greatest living singer of these American songs. A grateful posterity, listening to these records, may well decide that his choice was right,"—Life.

STORY'S SPECIAL OFFER

STORY, America's Literary Magazine, including in its contents the finest short stories available ("Address Unknown" caused a world-wide sensation, and now in book form is a current best seller—twelve of the stories in "The Fifty Best of 'O'Brien's Best' " are taken from STORY), novellas (long stories), outstanding literary comment and reviews, and interesting End Pages, Announces This Special Money-Saving Combination.

For only \$5 you may have a full year's subscription to STORY and the four Sandburg records. The records come to you, safe delivery guaranteed, in a handsome album with Sandburg's picture on the cover. Subscription may be a new one or a renewal. Records and subscription may be sent to different addresses.

The Great American Rite-By T. Swann Harding

The Public is Largely to Bleme for the Too Casual and Rou-

THE most intrinste part of a television receiving set is the rathode-ray tube, described in some detail on page 23 of this issue and illustrated during one process of manufacture on our front cover. Here the operator, a skilled glass worker, is sealing into the narrow neck of the funnel-shaped tube the "plag" through which pass the wires that form the electrical connections to the internal elements of the tube.

SCIENTIFIC AMERICAN, July, 1997, Vol. No. 181, No. 1, entered at the New York, N. Y., Peet Office as second clear matter June 23, 1479, under the ang of March for, 1979, additional entry at Greenview Comm. In the served, Subscription price \$6.00 per year. Canada \$4.50, Foreign \$4.50, Manuscript are schemicted at the author's cities and cannot be returned unless accompanied by posting.

OUR POINT OF VIEW

"Self-Sufficiency"

UNDER the title "In Case of War," 1936, issue, a discussion of those strategic raw materials which this country must import because we have little or none at home and which are absolutely necessary to the proper functioning of our vast industrial empire. The list of these vital imports given in that article totalled more than two dozen at the time of publication. There is today no essential difference in the number and kinds of materials in such a list, yet there has been a momentous change in the picture. Chemistry has provided satisfactory substitutes for some of them, found ways of providing nearer-home supplies of others.

In this issue is an article which summarizes starthingly the ends to which Europe must go in order not only to be Europe must go in order not only to the clee during a possible future war but also to assist in the present conomic war. A similar motor fuel problem will not have to be faced by the United States perhaps during the lifetume of present to to there are other, no less pressing problems to be faced and solved if we are to maintain our national economy with little duruption in tume of an emergency.

A wecond article in this issue serves to emphasize one problem which we do have—that of supplying rubber, which we must import, to a large number of motistries. More important, this article also gives a linit of what we are doing to face this situation. It shows that we, too, have creatiz materials; that is, substitutes for natural products. What people do not generally know is that the business of finding something of native compounding to take the place of searce or imported necessities is important in its own right. It is this that has changed the picture alluded to above

Synthetic resins are being need now where imported tin was interto indispensable; chromium and platinum are giving way to domestic alloying matetials; organic substances are used for rubber, silk, quinine, Manila filter, are opium; and improved processes are making available hithern unworkable deposits of low grade mangance ore.

So far, only a start has been made in this drive for a form of self-sufficiency. Yet an enormous effort is being made in this direction, and it can be stated positively that, in case of a future war, we will be in a much better position to supply the materials required by industry than most people imagine.—F. D. M.

Incomparable Promise or Awful Threat?

FOR years past, screnntic writers have been pointing on the fact that if the energy known to be confined within the atom could be practically and commercially released and employed, there would be power in amounts today unknown. A handful of atoms would suffice to drive a liner to Europe and back, for example. The atomic energy of a piece of coal burned beneath a boiler by a ratio of a whole bullion to one. Such writers have usually hastened to add that there was no prospect of mails 'sever unlocking these stores of power, and some have hinted that perhaps this was pust as well.

Once more the foolhardiness of predicting impossibilities threatens to be demonstrated because, as this is written, physicists are at work on experiments that seem to contain the possibility if not the probability that the billion-to one power source is at least within view. The uranium isotope 235, when bombarded with slow neutrons, releases inconceivable energy. Simultaneously it releases more neutrons and, if uranium 235 isotope be present in quantity, the result of this trigger effect is a chain reaction of far more than terrible power. Fortunately, uranium 235 is only one hundredth as common in the orcs as ordinary uranium 238, else exceedingly dire resultsexplosions of magnitude heretoforc unknown-would automatically follow unless proper control were provided.

Here, in this last clause is the question that is worrying the physicists. The minute a new force for man's benefit is found, individual examples of the genus homo begin plotting to use it as a destructive threat or in actual destruction for their own selfish, reckless ends. First impulse, then, among physicists is to abandon the experiments. Second thought shows that this would be merely to abandon them to these self-seekers, the war-makers and world conquerors. The physicist cannot stop. At first it might seem that, by an agreement, all the physicists could simply drop the matter and that this would end it. But the physicist is no more cer-tain in advance whether his discoveries will be a curse or a boon than anyone clse. He is a part of the stream of only slightly foreseeable human events. He cannot control his own discoveries, once they are given out, for he is far outnumbered. And if the human race won't leave its new playthings alone, and gets badly hurt, that's its own funeral, In a few years we may have the answer .- A. G. I.

Television Problems

COMMENTS, criticisms, suggestions, questions regarding television have been reaching this writer in increasing numbers since the beginning of regular scheduled television service in the metropolitan area. Two phases of the subject stand out above all others as being of great apparent interest to a large number of people. The first has to do with the service range of transmitters and the second with the possibility of constructing sets in the home workshop.

The service range of a television transmitter, under present conditions, is severely limited and that's all there is to it. With the extremely high frequencies that must be used to bring television signals into the home the range of the transmatter is practically limited to the optical horizon. Freak reception may be recorded occasionally beyond this area, but such freaks do not alter the situation as far as the average person is concerned. In other words, it must not be expected that the DX nights of early radio broadcasting will be revived in television reception. If you live within the service area of a television transmitter, you can enjoy television reception; if you do not, the only thing you can do is to wait until such service is made available in your locality. It would be useless, for example, for a resident of Texas to purchase a television receiver with the expectation of being able, even occasionally, to receive television broadcasts from New York City

Television receivers are admittedly expensive. They must be so because of their extreme complexity. This same complexity militates against the construction of receivers in the home workshop, although kits of parts are available for those hardy souls who will try anything once. Just because a person once built a satisfactory radio sound receiver, however, is no indication that he will be able to achieve the same degree of success with a television set. The skill required is far greater than that called for in constructing even a very elaborate sound receiver. Then, too, there is the element of danger from high voltages (kept under "lock and key" in commercial tele-vision receivers) that might lead the constructor into serious trouble.

Does all this seem pessimistic? It is not intended to be so, but rather is intended to present the facts as they stand. Television is bound to become an important factor in our daily lives; don't spoil it for yourself by starting off on the wrong fool.—A.P. P.

50 Years Ago in . . .

(Condensed From Issues of July, 1889)

VALUE—"I'll gave you a pound of metal and ordered you to make the most out of it, what kind of metal would you select? asked a well known jeweler. 'Gold, of course,' was the promp reply. 'I'd prefer a pound of steel,' asad the jeweler,' and I'd have it made into hair springs for watches. A pound of such springs would sell for an even \$140,000."

ELECTRIC CARRIAGE—"The accompanying illustration represents the application of a system of electrical propulsion for common roads, by means of which traffic is designed to be carried on without employing a railroad track, the steering gear being so arranged

that the wagon will automatically run parallel with the line of the conductors, ... The wagon body to which this improvement as a pilled is parily supported on a caster wheel, provided with a fork, portaled in the forward end of an extension of the frame of the body. Upon the rear sale, in this case carrying the drive wheels, as mounted a spur wheel engaged by a pinnon on the armature shaft of a motor secured to the main frame of the body. Above the road bed are suspended electrical conductors, supported by poles and brackets, and each wagon is provided with a trolley which rides upon a plan of the conductors, whereby connection is made between the motor and conductors, through a vertical shaft, the electrical switch being close to the driver."

DEVELOPMENT—"Mr. Ersatus Wiman, on the subject of telegraph and telephones, in an address before the New York Electric Club, recently said, among other things, that it was a great blessing that the telegraph and telephone were early divorced, because I do not believe that the telephone would ever have been developed to one-quarter the extent to which it has been developed if it had been deemedrat on the telegraph."

POISON—"According to Mr. Stanley, the arrow poison used by the natives of the Lower Congo district is made from a species of reasts found in that locality. The ants are dried, crushed into powder and cooked in palm oil. The exceedingly irritating properties of the poison are supposed to be due to formic soid."

ELECTRIC LIGHT—"Electricity on ships of war is purely an American idea, and was first tried on the United States steamer

Trenton in 1883 ... Soon after the system had been tested the vessel sailed on a three years' cruise, and attracted much attention as the first vessel affoat to be lighted by electricity. The success of the Trenton's experiment practically settled the question in naval circles."

TELEPHONE.—"Baltimore will be the first all-metallic circuit telephone exchange in the United States, and we predict that it will be without equal in the world."

HEART FAILURE.—"The American Analyst thinks it would be an excellent idea of physicians of the present day would invent some other reason for all the deaths which occur nowadays than heart failure. It is difficult for any one conversant with the organs of the human body to understand how any human being can die without heart failure, while the causes of the failure of the heart at death may be very numerous."

STREET RAILWAYS—"The hill recently signed by the Governor of New York, allowing the street railroad companies to substitute inchanical motive power for horses, is an important one. We hope in time to see it tead to a general use of electric motors on the roads in this city."

ELASTICITY..."Professor John Trowbridge . . . calls attention to the importance, from an engineering point of view, of making careful photographs of steel and timber at the point of rupture under a breaking load, suggesting that in this way we may learn something important on the mucb vexed question of elasticity."

WORSTED-WOOLEN—"The question is asked, what is the difference between worsted cloth and woolen cloth? The answer is: Worsted goods are composed of wool that has been carded and combed, while woolen goods are made of wool that has been carded but not combed."

AIR CONDITIONING AND LIGHTS TENDERIZE BEEF

AFTER a long study, initiated by the Kroger Found Foundation, scientus of Mellon Institute learned many things about the action of beef enzymes that 'ripen." or tenderare, it. The final result was developed ment of a process, which make prime cuts of even the toughtest beef, involving air conditioning and use of the toughtest beef, involving air conditioning and used for the Sterliamp, the ultraviolet ray destrupter of bacteria and fungi which was developed by Westinghouse. In the photograph, the ubulual ramps are on the right wall.

A strange sight to an American; a "filling station" for Rome's 85 wood-burning buses. Small furnaces, concealed in the rear of the buses, and charged with blocks of wood cut in small sizes (or coal or chargeal), generate the gas which the motor uses

Ersatz Motor Fuels

THE dominant note in Europe today is self sufficiency; the dictates of nationalistic forces have made production of all wartime supplies of great stimportance. Under such a regime the conomic side of the situation is sub-rodinated to the necessity of muontaning within national borders the means of carrying on war measures in the face of an extensive blockade.

To the army and air forces of a highing nation, more fuel is almost as vital as man power, and since most of the nations concerned are deficernt in oil supplies, the manufacture of sub-titute fuels has been forced to a new histosiace 1937. The villingness with which Europe accepts substitutes, which permit conservation and storage of gasoline against a possible war, points the way toward operation of all civilian motors on substitute fuel so that military machines may have the exclusive use of all Europe's Desperate Nationalisms Force Use of Native Fuels...To Conserve Gasoline for Possible War...Result: Enormous Net Monetary Losses

By GUSTAV EGLOFF
Director of Research, Universal Oil Products Company

gasolme. This would be the wartime ideal. Eighteen percent of the motor fuel consumed in Europe during 1937 consisted of substitutes for gasoline. The substitution substitution for gasoline. The substitution substitution was wood and coal to compressed gases of several kinds. Offland this might seem to indicate great saving since the cost of imported gasoline is extremely high in Europe as compared with gasoline cost to American motorists. By the use of substitutes, however, Europe but approximatorly \$235,

000.000 during 1937. This was an alltime high. Yet 1938 showed an increase up to 25 percent of all motor fuel used and a loss of about \$300,000.000 through subsidies and taxes

Americans who have heard much of the plan, in this country, to use alcohol as a blending agent with gasoline, will be suprised to learn that use of power alcohol in Europe is steadily declining. The same war scare that is promoting use of motor fuel substitutes is diverting alcohol to the munitong industry where

it is a vital raw material. Furthermote, calcobol in essential in wartime for medicinal use, and motors adjusted to use in peacetime would require costly readjustments to use other fuels when war breaks out. Already, there are insufficient supplies of alcohol in Europe, othat France and Italy were curtailing us use in 1937, while Germany not only twee reduced the mandatory percentage of alcohol in gasoline but also had to import supplies of it.

Even with declining use, with alcohol constituting only 4.3 percent of Europe's motor fuels in 1937, it cost Europe that vear \$104,040,000 more than an equivalent amount of imported, tax-paid gasoline. Other substitutes made up the remaining 13.4 percent and cost \$130,826,-000 more than imported gasoline. These losses are made up by the direct and indirect subsidies on native motor fuels, by special taxes on imported motor fuels, by partial elimination of taxes on native fuels and the vehicles using them. and, in some cases, by direct payments to operators of vehicles using native substitute fuels. As is the case in any country where any one group is aided by the government, it is the public-each and every individual—who pays, in taxes, the European motor fuel bill for the favored

WOOD, charcoal, coal, and lignite are used to make producer gas in generators on many European motor cars. Compressed natural and manufactured illuminating gases are carried in clumsy tanks on some cars. Experiments have been conducted in efforts to utilize acetylene, cracked ammonia, and hydrogen. Hydrogenated gasoline is, however, Europe's primary substitute motor fuel. While this fuel is actually gasoline, it is a manufactured productmom cities coal or carbon monoxide—and is subject to the limitations of factory production.

Hydrogenated gasoline is the only one of the various substitutes which is of possible value to the United States. Small

about 18 cents per United States gallon. When units now under construction and designed are added to those now operating in Germany, that country's production of hydrogenated motor fuel will total about 17,000,000 barrels per year. In England, the production is about 1,300,000 barrels a year; while France is operating only a small unit producing 110,000 barrels a year. These figures may be compared with the world production of gasoline from petroleum by cracking and distillation totalling 775,000,000 barrels a year and it will be seen that only a tiny dent has been made in the problem of supplying manufactured gasoline to supplant that from petroleum.

Combustible gases of many kinds-including natural gas and gases recovered from both hydrogenation processes, from coal carbonization, and from the cracking process-are being used more and more widely in Europe. In Germany, lightweight alloy cylinders have been develop-ed for attaching to motor cars to carry the combustible gas under pressure. These are picked up as replacements in filling stations that dot Germany, or are refilled at the stations with city gas, methane, or propane-butane. It is estimated that there are in Germany 25,000 vehicles using a total of about 250,000 such storage tank cylinders. Depending on the gas used, a given vehicle using two of the tanks will travel on one filling 25, 85, or 225 miles.

The use of compressed gas as a motor fuel requires conversion of vehicles, consisting of the installation of racks to carry the tanks, a regulating valve to control pressure, and a special gas-air mixer in

experimental plants are producing a small quantity of hydrogenated fuel in this country, looking toward the time when petroleum supplies will have become so nearly exhausted as to make neccessary a supplemental supply of fuel. At present cost of production, hydrogenated gasoline is-too expensive to use in America. In Europe, this fuel, whether produced by the hydrogenation of coal or of carbon mosoude, is believed to cost

place of the carbureter. To make this conversion, the cest may be from \$150 to \$300, depending upon the size and power of the vehicle. The number of tanks upon the vehicle varies from two to eight, depending upon the type of service; passenger buses may even pull trailers to carry the tanks. Each steel cylinder weighs 115 pounds empty and 215 pounds when filled with propase-butane at a pressure of 150 pounds per-square inch. This set of 150 pounds per-square inch. This set 100 pounds of gas is equivalent to 18 gallons of gasoline.

Perhaps the oddest motor fuel used in Europe, from the American point of view, is producer gas from wood and coal. Yet terials probably come nearest to being plentiful in some countries of Europe, relatively few vehicles burn gas made from them. Drastic laws have been passed to promote wider use of producer gas and government subsidies have been granted users, but there are even yet no more than about 9000 wood-burning vehicles. In France, Germany, and Italy they consume annually 450,000,000 pounds of wood. This amount is equivalent, in motor operation, to about 18,000,000 gallons of gasoline.

Some cars are built directly for using producer gas from wood, but more often gasoline types are converted by adding a stove to burn the wood, cooling pipes, filtering agent; tank to collect condensed water, tar, and acids; and sometimes a blower. The cost of this conversion may range from \$300 to \$500.

Georgemes, as the units are called in Europe, perate by hurning word, wood charcoal, coal, hgaite, or briquettes in a hight steel cylunder which may be lined with a ceramic insulation. The fuel is loaded in through an opening at the top and lighted. Air is admitted through an opening at the bottom, and the gases resulting from combustion leave the tank through another opening at the bottom.

The combustible gases are cleaned by pussing through cooling pipes to collect

At right: A Parisian taxi driver attracts currious bystanders as he loads his wood-burning taxi with a charceal-anthracine mixture. Relow: Motorman's cab and wood-burning gas producer in a French passenger bus. At bottom of page: A German bus which carries compressed gas fuel in trailer tanks

duction of France were used in this manner, it would still supply only 10 percent of the nation's requirements in motor fuel. The reduced efficiency, inconvenence, and delays in starting and for relatively frequent cleaning are other objections to the use of wood to make gas for motor fuel. Coal, in several grades, is more plenti-

Coal, in several grades, is more plentiful in Europe, and these raw materials, used singly or mixed in various ratios, could be used far more widely than at present in case of a national emergency.

Of the other substitute motor fuels used or tested in Europe, little need be said. In a number of countries, oil is being extracted from shale. This is a substitute, of course, only in the sense that it takes the place of imported motor fuel. In Italy, synthetic ammonia, after being cracked into narrogen and hydrogen, has been used as a motor fuel, but its low efficiency and high cost are factors militating against its general adoption. Acetylene has been tried and found wanting in several respects. Hydrogen, compressed and carried in tanks as is city gas, does not seem to be a satisfactory fuel.

LEARLY, gasoline would serve all motor needs in Europe more efficiently than these expensive substitutes and semi-substitutes, even under the prevailing strained economic conditions. Purely from a military standpoint, the huge loss of \$300,000,000 brought about by their use might be used to better advantage in purchasing and storing petroleum for wartime needs. The reason civilian populations will tolerate this loss is probably due to the fact that the burden is relatively small because of the smaller number of cars in proportion to population. In all of Europe, with a population of over half a billion people, there are only 8,189,335 motor vehicles as compared with 30,000,000 automobiles for the United States; or one car for every 63 people as compared with our one car for every five people.

water, tar, and acids. A dust catcher and a filtering chamber collect the colloidal particles of dust from the gas which is forced by a blower into the motor.

Despite its many disadvantages, the wood-burning motor has one point in its favor: the filling station can be any wood pile where good, air-dried wood is available. However, it takes about 25 pounds of wood to give the same distance perfermance as a gallon of gasoline. Many

wood-filling stations are scattered over France, Germany, and Italy and from them 30 to 60-pound packages of wood may be purchased. The cost is low, but any comparison with the price of gasoline is fictitious because of the several subsidies and taxes that enter into the question. Furthermore, it can be confidently said that gasogene vehicles will never prove a satisfactory saver of petroleum products; if the entire annual wood pro-

Lies-Truths

A murder suspect heing tested on the Polygraph the detector by the author. A rubber tube enterling his chest and another on his arm transmit fluctuations in his heetathing and pulse to the instrument, making record on a moving stru-

WICHITA, Kansas, sometimes is called the proving ground for the Keeler Polygraph or so-called he detector, for it is there that more persons are tested annually with Polygraph deception technique than anywhere else in the world.

The Webus instrument is owned and operated by the Police Department Each operated by the Police Poperatment Each bedetector tests, because of superteed crammal activities or because it is thought that they may be closely connected with certain craminal offenses accurately and painstakingly recorded and statistical data are compiled to measure the instrument's value in police work and to determine its accurately and inaccurately.

Since scientific he detection is comparatively new to police, and since at has only recently branched out into the commercial field, statistical data have been more or less limited and the techique of detecting deception has had to with-stand the usual doubts and prejudices met by things new. The first quetion aroused in the minds of those in authority is; "How does at work," Usually this question is followed closely by another: "What dependence can I place in such a procedure,"

The answer to the first question, of ourse, deals with the mechanics of the motrument, the thiories or facts upon which its operation is based, and the procedure used in applying the technique. This question was compreheninger. This question was comprehenitive Direction of Lice, "which appeared in this magazine in June, 1937, and will be given only a short explanation here.

Polygraph deception technique is based on the fact that certain emotional disturbances take place within the lody during attempted deception. These disturbances, when recorded, are discernible in the blood-pressure and respiration of the individual taking the test. The Polygraph instrument is so constructed that blood-pressure and respiration are recorded simultaneously on moving paper during the entire examination. The second question can be answered only by application of the acid test-ic-alis. Heretofore, sufficient statistics have not been available, and therefore a comprehensive and factual answer could not be given. Now, however, with 4000 recorded examinations on file and a complete research of cases made during the years 1936, 1937, and 1938, it is reasonably safe to state that the he detector is playing a most important part in weeding out the guilty from the large number of persons whom police find it necessary to mixetigate.

Sepregating the 4000 examined subpress into nints of "routhful" and "untruthful," at was found at Wichia that 3020 were ablis to produce "clean" records—those in which no deception was displayed, Of this number, 1600 were transvents or vagrants picked up in the athoral yate or found loutering about the city streets. They were questioned about crime in goneral, and usually were released upon the completion of records which indicated that they had not committed any crimes and that they were and 'wanted' by other authorities.

ON the other hand, 974 of the 4000 produced records which indicated that they were not telling the truth, From this number, police were able to secure 537 full confessions to the crime under investigation. Subtracting this number from the 974 in the supposed "untruthful" group, there still were 437 to be disposed of. Of this number, 287 were released because complainants refused to prosecute or because sufficient evidence to prove guilt was not obtainable. The remaining 150, police took through the courts. Of this number, 112 were convicted, 34 were acquitted, and four cases still are pending.

The foregoing figures, reduced to a percentage basis, show that 55.1 percent of those whose records indicated deception confessed their crime; that 74.7 percent of those whose records did indicate deception, but who did not confess, were successfully prosecuted in court;

THE he detector described in the accompanying article is one of four types discussed in The Journal of the American Medical Association (Chicago, Jan. 29, 1939, page 354), Where do he delectors stand in general? This is largely a mutter of ominion. One opinion, on the conservative side, is stated by the medical journal named above, which finds that many of these machines are being exploited by non-medical men although they involve the most complicated forensic clinical principles, and that sometimes instruction is too buef. The same tournal recommends the tollowing books on the subject: "Legal Psychology," by H E. Burn; "Lying and Its Detecnon," by John A. Larson in col laboration with Geo. W. Huney and Leonarde Keeler; "The Psychology of Feeling and Emonon," by Christian A. Reichsmid; "Trial Technique." by Irving Goldstein; "The Lie Detector Test," by William Marston; and "Scientific Methods of Crime Detection in the Judicial Process." by J. Edgar Hoover. -The Editor

also that approximately 3026 persons, who were either suspected of cime or came under police inheritation, were spared the necessity of long incarcerations to permit the police to check up their many-angled stories.

During the accumulation of these reords 31 persons, because of mental or physical ahnormalities, produced records which were considered uninterpretable by the operator. Otherwise stand, 99.9 percent of all persons examined were able to produce records upon which a defantic and immediate decision could be made.

Space will permit the discussion of only a few cases, hence random records have hern elected. Take, for example, the graph produced by a young man. A salesman had parked his automobile in the down-town district, hidden a bag of money in the glove compartment, locked both the glove compartment and the car doors and gone about his business. Returning some two hours later, he found the car broken open and the money gone. Later in the day police picked up this suspect. The young man vigorously denied any knowledge of the heft and was requested to submit to

Now that the Lie Detector Has Been Used by the Wichita Police for Three Years, How Successful Has it Proved? . . . A Progress Report

By THOMAS HAYES JAYCOX Polygraph ("Lie-Detector") Operator, Police Department, Wichita Kanaas

Polygraph deception test technique. The graph below shows a "close-up" of the subject's record where he was asked questions concerning the stolen money, Notice the violent deviation from the 'normal" in both the blood-pressure (lower part) and respiration (upper part). Immediately upon completion of the test, the graph was explained in detail to the lying young man. He confessed and led detectives to his home, where the stolen money bag had been cached

The lower graph presents the reaction m a general investigation where police had charged no definite crime against the subject. These tests are given to hobos, vagrants, and to known criminals who are checked up from time to time. The operator simply goes "fishing" with his subject and often the results are more than worth the time and effort expended

- 9 Have you stolen anything during the past year?
- 10 Have you answered all questions truthfully?

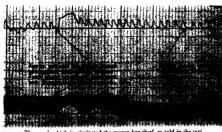

In a typical instance using these questions two young holos were brought in for tests shortly after they had alighted from an incoming freight train. Both young men steadfastly insisted that they had never before been arrested and that they had committed no crimes But their l'olygraph records had an entirely different story to tell. Notice in the graph the responses in blood-pressure and respiration (shown by arrows) at point 4, where one of them was asked the fourth question, "Have you ever committed any erimes and not been caught "" Notice how similar reactions were displayed at points 5, 6, and 9, corresponding to the respective numbered questions. Obviously, the young man was lying when he answered negatively to these questions. Interpretation of his reactions indicated that he had committed a crime and that the crime was burglary of a house or store, as shown by his answer to question 5. He was wanted by the authorities, or thought he was (shown in question 6) and he had stolen something during the past year (question 9).

With these deductions the operator proceeded to question the young hobo, and soon the facts began coming out. When apprised of his reactions, as shown by the instrument, and when their meaning and reason were explained to him, the hobo confessed. His home, he admitted, was in an adjoining state. He and his companion had left there only the day before. Just prior to their leaving, they had broken into a dwelling house and stolen a pistol. The pistol was neatly hidden in a roll of clothing he had been carrying under his arm.

These two cases, extracted from the 537 confession cases previously mentioned, do not by any means tend to reflect that the he detector is valuable only in nunor thefts or lesser crimes. Among the 4000 cases now on file are 52 murder investigations, one of which is the wellknown Wight case. To the he detector goes the credit for "cracking" this strange enigma and searching out the murderer from among nearly 50 suspects, as well as locating the murder weapon.

On the other hand, the he detector is not a panacea for all criminal ills. It is simply one of the many tools used in scientific crime detection and, like the doctor or physician, the operator is not immune from an occasional misinterpretation of the symptoms.

Yet with the 55.1 percent confession rate, and the successful prosecution of 74.7 percent of those who refuse to admit the truth, it is safe to assume that the lie detector, in police science, will average a high score in precision and accuracy. This assumption is true, however, only where a skilled and well-trained operator is conducting the tests. The instrument in the hands of a novice would be much like calling in a truck driver to diagnose some physical ailment-the recipient of his diagnosis would suffer.

The graph which incriminated the money bag thief, as told in the text

A questionnaire is used which includes nearly every type of crime listed in the statutes. For example:

- 1. Is your home in Wichita?
- 2. Do you live in Kansas?
- 3. Is this the month of ... 4. Have you ever committed any
- crimes and not been caught? 5. Have you ever broken into a
- house or store for burglary? 6. Are you wanted by the authornics
- anywhere?
- 7. Have you ever held up and robbed anvone?
- 8. Have you ever stolen an automobile?

Breathing and blood-pressure fluctuations of a hobo under questioning

THE FUTURE OF NAVIES

TEXT in importance to the capital ship discussed last month comes the aircraft carrier, that extremely vulnerable floating aerodrome the existence of which in wartime is looked upon as hazardous, but which many naval officers regard as likely to become as important as the battleship,

Carriers: Since the World War, progress in carrier flying has been such that landing accidents are very rare, and all the elaborate arresting gcar has been discarded. Very long and wide flight decks are still necessary-since in rough weather the pilot has to land amidships where the ship's motion is least and yet the plane may have a sufficient runwith ample beam so that an error in judgment, side-slip, or a rolling deck do not lead to a side crash. But "the bigger the ship the better the carrier" is no longer an accepted axiom, and both small and medium sized vessels are now being built instead of those of maximum dimensions so favored at the time of the Washington Treaty. A limit of 33,000 tons displacement, with guns no larger than 8-inch, was then agreed to, these limitations resulting in the U.S.S. Saratoga and Lexington and the Japanese Kaga and Akagi-inimense vessels carrying cruiser armaments and a considerable weight in waterline protection. When the Treaty came into force, Britain had just completed the Hermes of 10,850 tons only, steaming at 25 knots and having an official complement of but 15 plancs, while Japan had passed the 7470-ton Hosyo into service—a vessel of

In the Hermes, the deck was of sufficient width to allow for the funnel to be brought up through an island superstructure which an experimental canvas erection on the Argus-a clear-deck ship with side smoke ducts discharging at

By OSCAR PARKES

the stern-had shown to be a practical solution of the disadvantage of hangar heating, with restricted housing accommedation, experienced in both this ship and the Furious, But in the Hosyo, the deck was too narrow for this arrangement and recourse was had to small hinged side fininels which could be lowered to a horizontal position during flight work, as in the U.S.S. Langley, converted about two years after the Japanese ship was designed.

At the present time, both systems are in favor, while in the matter of size a considerable latitude is observed, depending upon the specific service for which the carrier is designed. Cost and vulnerability militate against maximum dimensions and the latest designs range from 10,000 to 23,000 tons with a wide variation in features dictated by national requirements.

THE huge 27,000-ton Kaga and Akagi, of Japan, have recently been reconstructed, the alterations including a lengthening of the flight deck by some 150 feet so that it now extends to the bows; shifting of the forward 8-inch guns formerly carried in two turrets on the lower flight deck to casemates in line with the other six such guns on the main deck aft; addition of many machine guns along the topsides; and, in the case of the Kaga, an alteration in her funnels. Formerly she had great trunks from the furnace uptakes amidships, along the outsides of the hangar, discharging as bell-mouthed vents aft: these have now been replaced by a brace of curious side trunks amidships below deck level, one of which curves up and the other down-a system tried out and retained in the Akagi. During flying operations, the down trunk is used, the furnace exhausts being discharged away from the ship by an admixture of pressure steam.

In the Ryuzyo, built between 1929 and 1933, an attempt was made to produce a carrier of small displacement but able to house 25 planes. Thus upon a hull 548 fect long and drawing only 151/2 feet, with a beam of 601/2 feet, a huge hangar was erected with six pairs of 5-inch guns and numerous machine guns along the topsides. She also had a pair of side funnels amidships and made 25 knots on trials. But, in practice, she has not fulfilled expectations, having proved a bad sea-boat; hence, in three later carriers, Sorvu (completed 1938), Hirvu (completing), and Koryu (building), some 3000 tons have been added to the displacement, yet the general characteristics of the Ryuzyo are retained. While in the Ryuzyo, the ratio of length to beam is 9 to 1 and beam to draft 4 to 1, in the Soryu it is 10 to 1 and rather more than 4 to 1, respectively, her dimensions being 6881/2 by 681/2 by 161/2 feet.

Most Japanese types appear to run to abnormal dimensions, and these ships seeni to be asking for trouble. Compare

Japan's 8500-ton cruiser Kumano mounts five triple 6-inch turrets. Torpedo tubes are in curious ports by the main mast

them with the U.S.S. Wasp, of 14,700 tons, which is of the same length as the Soryu but has an 81-foot beam and draws 20 feet! Moreover, the Wasp's length is "water-line" whereas in the Japanese ships it is understood to be "between perpendiculars," so that the overhang of the stern from sudder pintle to counter must be added-probably another 30 feet. Such a long, narrow, and shallow hull, surmounted by a great wind-trap of hangar, does not appear to be a very happy conception, although the Japanese designers aim to increas stability by a marked flaring of the hull for three quarters of its length and the fitting of gyro-stabilizers,

These '10,000-ton Japanese carries are reported to carry 30 to 40 planes, lave a designed speed of 30 knots, and mount 12 5-mch guns. More weemly looking than the Ryuryo, their sides have been spared that bookage of sponsons, platforms, pillar supports, and cluttered control positions which disfigure that ship; the funness are small trunks on the starboard side only. Apart from a small patch of armor over the engine and boiler rooms, they are unprotected against surface attack although well armof for sky defense, and well represent a type of small carrier which has many advocates.

In the Ranger (completed 1934) the Construction Bureau of the U. S. Navy provided accommodation for 75 planes in a ship of 14,500 tons with a speed of 29 knots and armed with eight 5-inch guns. An island superstructure with bridges, control positions, and a light tripod mast was placed on the starboard 'midships, with three hinged funnels on each side toward the stern. The leeward set are used to keep the deck free from smoke and heat eddies, Following her came the Enterprise and Yorktown of 19,900 tons each, carrying over 100 planes at 34 knots. These are generally enlarged editions of the Ranger but with a much larger island built around a most imposing funnel as in the Saratoga. These ships have catapults on the flight and hangar deck forward so that aircraft can be shot off without having to raise them to the upper flight deck. Frotection is limited to an armosed deck and some plating amidships over the boiler and engine rooms, sufficient only to keep out small projectiles since their metier will be to avoid action and rely upon a protecting screen of ships.

A return to smaller dimensions has been made in the Way and Homet, now building, which are 14,700-ton vesselvhousing 75 planes. Presumably each are allowed in the are a island superstructure and fundl to stat board, as this appears to be best solution of the furnace uptake problem when practicable. There will be same armament of eight 5 melt guns; and they again are intended to be carriers pure and simple in distinction to the new Genman craft.

THE German Graf Zeppelin, recently launched, and "B." still on the stocks. were laul down in 1936 and are Germany's first attempt at carrier construction, which was forbidden to that country under the Versailles Treaty. Actually, so long as her naval operations were confined to the Bultic and North Sea, she had no need of such craft, as shore stations could provide the formations required in these waters. Neither was transport required to overseas stations, as she has none. Hence, when it was decided that a ficet air arm should be built up, the question as to what type of carmer was needed called for special considerations. Freed from coast defense duties, the new fleet was intended for the high seas, and guerre de course was to be the main function; hence carriers would have to be specifically designed to that end. They might act in company with the big ships, or on their own after being escorted through blockaded areas either by surface ships or submarines or both. Yet when attacking convoys, they would be compelled to face enemy escorts of certainly cruiser tonnage; to fight with any prospect of success, a cruiser armament, in addition to a heavy sky defense, would be a first consideration. To keep out the enemy's shell and to localize hits means armor and subdivision of the hull proper by heavy plating, which absorbs a lot of tonnage; high speed under economical power means a long ship, with adequate beam and draft for proper sea-going qualities in the Atlantic, and a high freeboard. There would be no call for a very large unmber of planes to be carried, while a small target would be a sensible advantage. Therefore hanger space was limited to 40 planes. Working upon these death-create the Cermans have produced a new conception which is bound to influence naval warfare very considerable.

Displacing 19,250 tons, the Graf Zeppelin is 820 feet long between perpendiculars-about 70 feet longer than the Yorktown (p.p.) -881/2 feet in beam, and 181/2 feet draft. The hull is simple and plain, four decks high, surmounted by a two-deck superstructure along which runs the flight deck, This falls short of the bows as in the Ranger, so that a hangar catapult is probable, apparently there are to be catapults on each side of the flight deck forward. Sixteen 6-inch gins will be mounted, two aside in deep embrasures up forward and again in sponsons towards the stern, with the rest-so it is reported-in twin turrets fore and aft of the island superstructure as in the Saratoga, These guns will all have high-angle elevation. Ten 4.1-inch and 22 smaller anti-aircraft guns make up a splendid all-purpose armament. fitting her for cruiser duties or for beating off air attack.

Forty planes will be carried by the Graf Zeppelin and 'B" and the designed speed is 32 knots. No details as to protection are a saliable but launch photos show an end-to-end armor belt and their hulls will probably be built on cruise principles. From these details, it will be seen that, when operating on the trade crutes, these two ships will introduce novel and difficult problems in the matter of counter measures.

Incidentally, it has been disclosed that Germany's planes can be equipped for mine-laying, the mines either being dropped form the air at low allitudes or released from sepalanes riding on the surface. The torpedo planes have 16-inch and 17.7-inch torpedoes bloaded with 330 pounds of T.N.T. and 400 pounds of Novit, a new explosive. These are released at 20 to 50 feet above water, and both types have a range of 2200 yards at 45 knots with gyroscopic adjustment such that they run in straight, ziezar, or

Setting the destroyer pace, France's Mogador, a "cruiscrette," mounts eight 55-inch guns and makes 39 knots

spiral courses. High explosive bombs vary from 110 to 1100 pounds, and therare armor-piercing bombs, gas and phophorus bombs for use against personnel, and delayed-action 110-pound bombs for antisubmarine work.

Having laid an experience of something like 20 years in the design and construction of carriers which has covered a wide variety in types, and every opportunity in the matter of trial and error over a wide field of experimentation in design and equipment, the British Admirally has seen fit to revert to a type even larger than the Courageous which, a few years ago, was considered as an 'out-size' not likely to be repeated The 22,000-ton Ark Rojal has recently been passed into service and five more about 50 feet longer and 1000 tons heavier are now on the stocks

This latest type of carrier is 800 feet ong over all. 94 feet beam, and 23 feet mean draft, that is, about 88 feet shorter and 11 feet narrower than the American and 11 feet narrower than the American aircraft and an armament of 16 4 5-inch dual purpose guns, a sky defense of swinnlighe pompons, and cight multiple machine guns. According to present standards of arming, this is a very heavy equipment, but could only be used against destroyers and aircraft.

The effect of eight-barrelled pom-poms against destroyers has yet to be experienced, but in the opinion of torpedo officers they will have a devastating effect, being able to pierce plating and beilers, gun shirdas, and piping with such an overwhelming insilade that no previous experience will rapid-fire guns can be compared with it. The writer has seen a multiple pom-pom battery open fire a pulpor radio-controlled arcraft at such a beight that they could be followed only with a powerful pair of glasses. There was a thunderous rolling—not the expected stacets of machine guns, but a poeted stacets of machine guns, but a

continuous roar. In a few moments, a plane was twisting and tumbling down from direct hits, and was retrieved riddled.¹

The 45-inch is a new (aliber, fust mounted in the 1th Royal, which would appear to be rather an unnecessary substitute for the 47-inch. These guns are paired behind shields in side sponsons just below the level of the flight deck and have almost uninterrupted arcs of sky fire.

Sixty planes are carried in the Ath Royal, the hangais being arranged on two decks with three lifts transporting them to the flight deck. At the bowwhich flares out to almost the extreme width of the deck-there are two cutapults, with the deck between them ramped down to give a clear runway. The stern is quite an extraordinary structure with the end of the flight deck carried aft far beyond it as a fan-tail to facilitate landing. Apart from having a plated-in forecastle and stern section, the Ark Royal resembles the Courageous and. being actually a deck higher than the Saratoga, presents an immense target. Otherwise, she has no special points of interest in general design.

The French Joffre and Painleve, now building, are to be of 18,000 tons and are reported as designed for 32 knots. No details are as yet available and they will not be ready until 1941.

Italy has no need for carriers, as the Mediterranean can be covered from her shore stations.

Cruisers In designing her cruisers, Japan has sought to compensate for an agreed interiority in numbers, under the Naval Treaty, by installing superior armament in each ship. This has meant, in general, an increase in length to accommodate more turrets, with additional beam to give stability, and a necessary reduction in draft to keep displacement within Treaty limits. Her low free-board hulls, well sheered forward and tailed down aft, flared at the lows and along the water-lime, surmounted by wend tower masts, a serried line of turrets, and wildly raked and twisted funnels, present profiles which cannot be mistaken

In the six ships of the \$500-ton Magam class, commenced between 1981 and 1935, was insoluted an armainent of 15 distribution that the six ships and the wing catable, all of which, in conjunction with a long center-castle and considerable plannjer in the nature of bridgework, made the first of the class insatisfactors exabouts. The two last, Tone and Thuma, will carry only 12 6-inch guns, and have been considerably modified in other ways in order to regain the first consideration of all warships—sea-going abilities—

Five other cruisers are also reported as being under construction. These are 7000 tonners and by Japanese standards could carry 10 6-inch or a greater number of 5.5- or 5-inch guns. The 100pound, 6-inch projectile has always presented a handling difficulty for light weight Japanese seamen, and this caliber was retained only because of the adoption of power-loading. But, since power in place of human energy means a great increase in both cost and displacement, a reversion to a smaller, faster firing, man-handled gun, which is almost equally efficacious against present-day featherweight hulls, is probably being considered in Japan for the new 7000ton ships as it is in Britain for the Dido class

Such cruisers would make admirable commerce raiders or convoy guardians and it must be remembered that, in wartime, Japan will be vastly concerned with the malaneance of communications between her ports and the mainland of China whence all supplies of necessary minerals will be drawn. Four 8000-ton light cruisers were in cluded in the 1937 United States program and these Atlantas are to carry 12 6-inch gams of mly 47 caliber as against the 53-caliber, 6-inch gams in 80-maha, the aborter precedeing a dual-purpose of the state of the second state o

In England, at present, there are 21 light cruisers under construction of which the Edinburgh and Belfast are en larged editions of the 9100-ton Southampton class. They carry the same armament of 12 6-inch guns but the after turrets are a deck higher and the boilers are moved 50 feet aft to bring the catapult between the fore finnel and the hangar. Considerably more interesting are the nine Fig. class of 8000 tons, but also armed like the Southampton and steaming a knot faster-the first British cruisers carrying an adequate gun power for their tonnage to be built since the War. In the four triple turrets are 12 6-inch guns, with eight 4-inch anti-aircraft guns amidships and multiple machine guns on top of the hangars each side of the forward funuel. There is a patch of armor amidships over the engine and machine rooms, with continuations fore and aft along the waterline 1 to 5 inches thick, with 2-inch armor on the turrets, so that these ships have a very fair measure of protection. Speed will be 33 knots with about 1700 tons of oil fuel.

The 10 ships of the Dido class, of 5450 tons each, represent a small, cheap, and well-armed type which can be hult in quantity—a very necessary qualification for a cruiser design. They are slightly enlarged editions of the Arcthusa—which carries aux 6-inch guns and is not very favouably recarded. In the new ships, a

larger armament has been achieved by the introduction of the \$2.5 inch gun, ten of which are mounted in five twin turreds, there being forward on stepped levels and two aft so that say guns can fire head and four astern with wide ares on each beam. Naturally, such shape can be solved by lightly practeed, having Jische gun-louse armor and 2-inch plates amidships, plus the install armor deck below water. With engines of about 70,000 horsewer, the designed speed is to be 33 knots, are the designed agency in the 33 knots, as standard British figure for envisions.

There are under construction three medium size French cruisers of the De Grasse class, which will be more or less replicas of the British Fin-8000 tons. carrying 126 mch guns in four triple tor-1ets, eight 3 5-inch anti-aircraft guns, and four planes. No details as to protection have been issued, but these ships should be almost as well atmored as the Gloire class recently completed, with 3 to 41/2inch plate over the engines and boilers. 214 inch decks, 51/2-inch on turret faces, and 2-mch sides. Within recent years, France has been obtaining very good value for her displacement in all classes, and the De Grusse promises to be an excellent investment

I IP to now, the Treaty has limited Ger man cruisci displacement to 6000 tons and 5 9-inch guns, but in the vessels now building, her constructors have gone to 10,000 tons and 8-inch guns for the Blucher and Scydletz classes and 7000 tons for a group of medium size mounting 5.9 inch guns The Blucher and Admiral Hipper are 640 by 70 by 151/2 feet, compared with 588 by 6134 by 191/2 feet of the American Astoria, and will carry eight 8-inch guns in four turrets with 12 41-inch guns and 12 torpedo tubes There will be one catapult and three planes, with hangars anidships. A high speed is not aimed at but with the new, very high pressure boilers, which require about two thirds of the normal hull space, a speed of 32 knots is expected. Launch photos show, from first to fourth turrets, a main-deck belt which is said to be 5 inches, with light bow and stern continuations—in which case they will be the best protected of the Washington cruisers aftest

The second group, Prinz Eugen, Seydhtz, and "L," arc 6541/2 hy 71 by 15 feet, being longer, broader, and with slightly less draught for the 10,000 tons. A few months ago the writer was informed that the Blucker class were being changed to nine 8-inch guns, but as the name-ship is retaining her original armament, it is possible that the Prinz Eugen trio will carry the heavier armament in three triple turrets. It is worth noting that in these ships the Germans have increased beam and diminished draught beyond even the Japanese ratios, and their sides are markedly flared amidships as well as at the extremities, so that, as sca-boats, they would seem more suitable for the North Sea than the Atlantic.

Of the four 7000 tonners, nothing is known except that they will probably carry mae 59 meh guns Blucher and Happer are to be completed this year but "M" and "N" (7000 tons) were not laid down until 1937 and 1938, and "O" and "P" are to be legun this year, so that none of these may be expected to join the strong until 1940 or 1941.

Since the completion of the two Italian Garibaldis in 1937, no critisers of large or medium size have been laid down, but a new type of fighting ship has been evolved in answer to the French 2884ton Mogador class which might be called "cruiserettes." These 12 vessels, of the Regolo class, are enlarged destroyers, or scouts, of 3362 tons armed with eight 52-inch and six anti-aircraft guns and eight 21 inch tubes, engined with 120,000 horsepower for 41 knots. They are the first warships to have a designed speed of over 40 knots. Their dimensions are: 114 by 14.7 by 13 feet so that they will be shorter, beamter, and shallower than

The British 8000-ton Fiji class of crulser: 12 6-inch guns, good armor protection. Hangars beside forward funnel

Britain needs a host of small escort vessels, such as the Black Swan, for convoy purposes

the French ships, assuming that the length is between perpondiculars. They are essentially Mediterranean ships, able to make a very high-speed gue- and torpedo-attack with weapons of cruiser calber, but without the seegong qualities of a cruiser or her radius of action At present, they mark a very interesting link between the cruiser proper and the do-stroper—an upto-date model of the "scout" which has appeared sporadically in most navies at one time or another.

Destrovers: As already noted, the line of demarkation between cruisers and destrovers has now almost disappeared The French Mogador mounts eight 5.5inch guns and 10 21-inch tubes and, with 90,000 horsepower, has exceeded her 38 knots. With guns able to exceed 25,000 vards with a maintained fire of 16 rounds. a minute, she is a most formidable craft. The French now possess 32 ships of her general type. They are employed both in the Channel and Mediterranean and have led to the Germans enlarging their destrovers to 1811 tons, to carry an armament of five 5-inch guns in single mounts and eight 21-inch torpedo tubes, and to steam at 36 knots. Thirty ships of the German Von Roeder and Maas classes are now built or completing. These have been countered by the British Tribal class-1870 tons with eight 4 7-inch guns and only four 21-inch tubes - - in which torpedo equipment has been sacrificed for gun power As destroyers proper, the British have 14 of the Javelin class building and seven of the Lightning class recently laid down, the former being of 1690 tons and the latter of 1920 tons, with a common armament of six 47-inch and eight to ten 21-inch tubes. Just how the extra tonnage of the "L" class is to be utilized remains to be

seen-probably in increased anti-aircraft

For many years the Japanese have been in the forefront in destroyer design and since 1926 have, year by year, been adding to their flotillas heavy-weights carrying five and six 5-inch guns with six or eight tubes and able to steam at 34 knots They were the first to give gun-house protection with high angle mounts, and to protect their torpedo gunners by shields. They also developed an exaggerated form of bridge, crowned by a heavy range-finder, and generally piled on topweight until the capsizing in 1934 of the Tomoduru (afterwards salved) led to a general criticism of this trend in design and a return to less extreme proportions in hull and curtail-ment of superstructure. In the eight units now building in the Kurosio class of 2000 tons the Japanese have followed the French and Italians in merging the destroyer with the light cruiser and producing a "cruiserette" carrying eight 5-inch guns and with 34 knots speed— which is well below what the United States and European Powers deem necessary for this type. But with an armament almost equivalent to that carried in Italian and French vessels of some 900 to 1400 tons greater displacement, they can afford to dispense with that extreme speed suitable for Mediterranean tactics and conditions; for Pacific purposes they should be compared with the U.S.S. Somers, of 1850 tons, mounting eight 5-inch guns and twelve tubes, steaming 37 knots, and carrying 500 tons of fuel.

Following the 12 Maury class destroyers of 1936 (U.S.), come the 12 Sims and 16 Benson classes now under construction—the latter being of 1620 tons and generally resembling the standard one funnel Maury class but with six 5incli guns in pairs in place of four singles, and the extremely leavy torpedo armament of 16 tubes, of which eight fire on each beam. American designs favor the practice of stowing all torpedoes in their tubes on deck rather than carrying half the number of torpedoes on the center-line and keeping spare ones below deck.

Submarines and Auxiliaries: As regards submarine construction, no departures from the orthodox designs have been produced by any Power, although it is reported that a Russan boat of very large size—over 3000 tons by estimate—has been seen in the Black Sea.

The British, faced with the necessity of eccorting a vast overseas traffe, have steadily added small escort craft to ther Home and Dominion navies, of which the Black Swan is the latest sample. Of 1250 tons, she mounts four twin 4-inch dual-propes guns and, with 3600 horsepower, will steam at 19½ knots. She is designed to accompany a convoy through the submarine and aircraft zone. The earlier British excort vessels were very poorly armed, being first intended to be mine-sweepers, but are now down for re-armament with six or eight 4-inch guns. Hosts of small craft-minelayers,

Hosts of small craft-minicalyers, motor torpedo boats, and so on—are being added to the European navies, but space precludes more than their mere mention. These brief descriptions of the capital ships, carriers, cruisers, and torpedo craft being built by the Powers give some indication of the tremendous activity being devoted to piling up offensive and defensive aquadrons in preparation for the hostilities now threatened through territorial demands by Germany and Italy with Japan at the Far Eastern and of the "Atal."

AIRPLANES, UNLIMITED!

THE flying machine, in an age in which automobiles roll off the assembly line like shelled peas into a basket, is still hand made. In some stages of assembly, it takes two men four hours to rivet a single square foot of a metal plane's surface. In peace time, this deheiency of our most modern transport.

and military device is a machine-age paradox; in war, it might be a calamity. For years our air corps officers, aircraft designers and huilders, and avation experts, reseming this production lag, have been praying—more fervently than ever since Munich for some method of producing planes as rapidly as automobules.

Their prayers seem about to be answerd. A new technique, developed primarily by Col. V. E. Clark, veteran designer and our Army's chief aviation engineer during the World War, and secondarily by Dr. Leo Hendrik Backeland, the father of modern plastics, with the co-operation of the Haskelite Corporation, of Grand Rapids, makes possible (unless all signs fail) a practically unlimitted supply of stout, unlimited supply of stout.

cheap, fast airplanes For a year and a half a mystery ship, cream-colored with a vermilion stripe, had been haunting eastern airports from Florida to Quebec, undergoing all sorts of weather, as well as static, impact, and vibration tests. Then, in the course of a Congressional monopoly investigation last winter, Dr. Backeland's son. George W. Backeland, a World War aviator and aviation enthusiast, under fire of a quiz into patent relationships in that giant industrial stripling, plastics, digressed from his testimony long enough to reveal the existence of a laminated plastics plane fuselage which he said could be moided and made ready for the assembly line in two hours, half the time needed to buckle on a single square foot of the present airplane's skin. This was the cream and vermilion "Clark 46." Headlines flared briefly, but Colonel Clark, returning from Europe, squelched the sensation by wireless from his ship at sea. Only now, after months of gruelling tests, does he feel that his plane's Molded Fuselages and Wings Make Possible Mass Production . . . Plastics Employed . . . 36,000 Planes a Year . . . Tremendous Wartime Significance

By FORREST DAVIS

A hint of the future: The fuselage of this plane is molded from laminated plastics in two shells, can be manufactured economically in mass production, has been subjected to severe tests

performance justifies a public report on its nature and implications. This report I am authorized to make.

HOWEVER the January revelation struck the average newspaper reader, it was no news to rival designers, to builders, plastics researchers, or the National Advisory Committee for Aeronautics. Nor did it surprise the air ministries of certain European powers apart from the Rome-Berlin-Tokyo axis. Insiders here and abroad knew that Clark, a distinguished designer who, among many accomplishments, devised the airfoils, or wings, for Lindbergh's Spirit of St. Louis, had been working at Hagerstown, Maryland, on the mass-production problem. Some even recalled that during the World War he instigated experiments on a molded plane; an attempt which was abandoned after the Armistice because the technicians had been unable to form plywood in permanently smooth compound curvatures and because the adhesives then known failed to protect wood from deterioration,

Few doubted Clark's eventual success. Here was no eccentric, long-haired inventor, but an able aeronautical engineer rated high in Wall Street as well as in his profession. His backers, since he tackled the big job in 1934, include some of the most noted industrialists and financiers in the country. Furthermore, a general feeling existed that the time was ripe for fundamental advances in the laggard art of airplane fabrication. If Clark didn't lift the curse of Adam from the industry, it was felt, some one else would and pretty soon. New, synthetic resins brought out by the plastics laboratories had given aviation, as well as a host of other crafts, novel materials and tools.

Early planes were contraptions of doped silk, spruce strips, wire, and bamboo poles. The war brought plywood or veneers bound with animal or casein glue. Plywood was, and still is, unsatisfactory, since it is virtually impossible to protect

Left: Side view of the "Clark 46," showing the sleek lines of the molded plastics fuselage. In this model, the wings are of plywood, to furnish compari sons between the two materials under operating conditions, Below: A close-up view of the molded fuselage, showing absence of rivets and other projections

wood against rot, fungi, moisture warp, and check, In 1929 arrived the light, allmetal alloy plane, which made possible transatlantic clippers and the 350 mile-an-hour pursuit ship. But the inside of each wing, each fusciage of an all-metal plane is a forest of carefully calculated stiffening frames and stringers; the outside is peppered with thousands of rivets It takes weeks, often months of the work of many skilled hands to complete such a plane. The great Douglas plant, under forced draught, needs 18 months to turn out 500 ships for the British.

NOW examine the "Clark 46," which in time may relegate metal planes to the shelves of history. Its fuselage is sleek, glass-smooth, and rivetless. There are a few discolorations and nicks on the belly, made by stones cast up from the wheels. (In the case of a metal fuselage, stones striking its underside leave noticeable dents) Otherwise its perfect flanks give no indication of the 1600 hours it has spent in the air, deliberately exposed to every flying stress and strain, to every onslaught of rain, sleet, and snow. Rap on it, and wonder at the light, unsubstantial sound. Peer into the dark interior. climb into the cockpit, and notice the complete absence of structural supports. All the space is free. And there is only a faint seam to show where the two 20foot half-shells that form the fuselage were joined together.

Colonel Clark has given the name "Duramold" to the new material from which this fuselage is made Manufactured by a secret process employing phenolic resus discovered by Dr. Backeland. Duramold, roughly speaking, is a laminated plastic similar to the glossy table tops and decorative panels often found in night clubs or cafeteria bars.

Technically, Duramold stands somewhere between the plywood built into airplanes between 1917 and 1931, and a true plastic. The difference between a

laminated and a true plastic is this: a laminated product uses organic fiber, such as wood or cotton, for its base, and employs resin as an adhesive, a forming, and a coating agent; whereas the true plastic has resin as its base and may or may not use fiber as a reinforcing filler. Practically, a true plastic requires high temperatures and enormous pressures for forming. Duramold is molded inexpensively in a die. Exactly how this is done can not be explained since the secret is well kept, I can only reason that thin strips or slicets of plywood, of long straight grain, are formed into the desired curvature, that they are then fixed into a mold, partially impregnated with a phenolic resin, and then pressed into a cohesive mass that is no longer wood nor synthetic resin but virtually a new synthesis

Duramold does not chip or corrode; it resists water, oil, and acids; and is stronger than metal, Says Colonel Clark:

"In the form of a simple thin-walled cylinder of given weight under compression, Duramold is, roughly, 10.4 times as strong as stainless steel, 3.4 times as strong as aluminum alloy, and 12.1 times as strong as reinforced solid phenol for-maldehyde resin (a plastic)." Its basic ingredients are cheap and, in part, absurdly common. Set in molds, Duramold can be given any desired shape-and will keep that shape.

The shape of a plane is all important. Experts in aerodynamics know that tiny bumps or depressions measurably interfere with the flight of a plane. In metal planes such flaws are hard to avoid; in planes of Duramold, true to a few tenthousandths of an inch, there need be none. Engineers have said that the "Clark 46" is, aerodynamically, the most nearly perfect plane they have ever flown.

And only the fuselage of the "Clark 46" is Duramold. The ailerons and rudder are of alloy; the wings are of improved plywood—used partly because a plastic fuselage was sufficient for experimental purposes, and partly because Colonel Clark wanted to compare the behavior of the two materials. Even laymen who have examined the plane have remarked the fact that, while the Duramold has stood the tests of 20 months, the plywood lass not. The wings, applied in sections—not molded on two longitudinal parts like the fuselage—show signs of repair. One joint has been damaged by the weather—or by rot.

Within a few months we shall see a plane in which wings as well as fuselage are made of Duramold, for the wings are no more difficult to fabricate. At the present stage of this new process, Duramold may be pressed in lengths no longer than 40 feet, giving a wing spread of 85 feet, ample for most military purposes. Duramold planes will be as strong as metal; more fatigue resisting, it is believed, as safe in the air; and probably less hazaidous in a crash, since wood breaks more slowly than metal under impact Under gunfire, Duramold fuselages and wings will fare better than metal once because they will have no vital structural points to be shot away.

DECAUSE of its seamless, rivetless skin, a high-speed, all-Dutamold plane will have a frictional drag no greater than glass, and will be theoretic ally 7 percent faster than its all-metal counterpart. At 300 miles per hour, this would be a gain of 21 miles.

But the revolutionary feature of this new process is, of course, the speed of manufacture At the Haskelite plant in Crand Rapids, nine men molded a half section of the "Clark 46" in one hourtwo hours for the whole member. Shipped to the Fairchild factory, only 5 hours and 20 minutes were required to assemble the entire fuselage and fit it, without filing or drilling, to the completed plane. And this, remember, was an experimental job In factory production, when that comes, the time will be cut down even further. There is no reason why Duramold wings and fuselages may not eventually be turned out as rapidly as Fords.

Colonel Clark undertook his researches as a preparedness project. Having learned a lesson from our pitifully inadequate air building program during the last war, he foresaw a period of heartbreak for the air arm in the next war while production awaited the slow, manual job of fixing stringers in airplanes and fastening them with millions of rivcts. The answer was the elimination of stiffeners and rivets, Sherman Fairchild, of the Fairchild Aviation Corporation at Hagerstown, shared his views; the chemists of the Bakelite Company advised; and the Haskelite Company, a laminated plastics firm at Grand Rapids, gave invaluable aid based on extensive experience which they have gained in the highly specialized field of plywood fabrication.

Personally, Colonel Clark is a wellgirthed, patient-woeed gentleman of \$3, with kind manners, an abstracted air, and blue eyes as cold as calculus. Born Uniontown, Pennsylvania, and cliristened Virginus Evans, Clark went to Annapolis, transferred later to the Army's Coast Artillers, fually to the Avauton Section, Signal Corps. At 29, he was made chief

Col. V. E. Clark, veteran airplane designer, who is proneering in the field of laminated plastics planes

engineer of Army avaiton, a post he held throughout the war and until he retired from the Army in 1920 to become chufceronautical engineer of General Motors at the Daytou-Wright plant. When General Motors withdrew from avainon in 1923, Colone Clark helped organize and became chuf-engineer and vice president of Quanolidated Aircraft at Buffale, designing and building more than 800 training ships there for the Army and Navy.

From the standpoint of national police, the use of Duramold, or other early obtainable plastes materials, would frequence on aluminum alloys. But what is note important, the Clark method may realize the long-standing dream of air planes as cheap and accessible as automobiles. It is not inconceivable that Clark might nor day be the Ford of the sky-ways. The fact that production of plastic airplanes have no observable limits gives his caterprise exciting scope at this juncture in European affairs.

Nazi Germany terrified the world by turning out 10,000 metal planes in one year. The democracies—including ourselves—here that it would take months, perhaps years, to overcome this preponderance. We can tumble airplane motors, instruments, propellers, fittings off the assembly line. But production logs down in the bottleneck of the great structural parts, with their thousands of man-hours and millions of rivets. The German war plane program calls for 160,000 skilled workers in the arrplane plants alone, plus 240,000 more to make parts and metal sheeting, Duramold planes will break the bottleneck. With ten sets of dies, two foundered men in a factory overring one city block could baild enough Duramold fuselage, wing, and tail shells for 300 planes a month; with 100 dies, 2000 workner, only semi-skilled at latt, could, in one year, mold and assemble 36,000 Duramold planes.

THESE things are just around the bend of the future, Colonel Clark, long a pioneer, has rivals Glenn Martin. who built hedgehoppers contemporaneously with the Wrights and Glenn Curtiss, has been conducting research in his Maryland plant for two years, and has established a fellowship at the Mellon Institute under Dr. William L. Rast, with the hope of evolving his own plastics type ship. Another group with a dozen chemists and engineers is at work at Hasbrouck Heights, N. J., under Eugene L. Vidal, former Director of Aeronautics in the Department of Commerce. They have already molded scaplane poutoons which are now being tested by the Navy. In Europe, the race for solution of the problem of mass production planes is furious, the contestants being England, France, Germany, Italy, Holland, and the U. S. S. R. The English De Havilland Company leads in research, Plastics propellers-lighter, stronger, and cheaper than metal-are being produced in England and in the United States. The German Heinkel Works is supposedly making three planes a day of plastics plywood panels-which is primitive compared with Colonel Clark's achievements. Another German firm is said by the British Aviation Journal, The Aeroplane, to be installing 12,000-ton plastics molding presses, possibly large enough to form structural airplane parts. The implications of all this are tremendous When the new science of plustics has helped solve the problem of mass production of planes, the winged fear that made Mnnich possible need never be repeated No one nation will be able to cow another from the air for long. Portugal and Peru, if they wish, may have air fleets as large as those that terrorized Europe last September. Preponderance in aviation may give way to equality; planes may become as commonplace and unimportant in the balance of war and peace as rifles are today. The only possible superiority in the air may depend on morale, flying skill, strategy, and a ready supply of petroleum. If peace lasts until plastics planes are as much a reality as Fords, their sheer quantity may help to keep the peace. And to peacetime avia-tion, their cheapness, durability, and steadiness may open up as yet undreamed of vistas.

WHAT KEEPS THE STARS SHINING?

READERS who have had the patience to follow our story of stellar energy into a third installment may be excused for asking what dramatic conclusion justifies so long a tale. So far, we have built up the situation, and shown that the climax of the play must be a transformation scene, in which atoms of some kinds combine and change into atoms of others, with liberation of the energy which keeps the stars shining. This atomic-or, rather, nuclear-interplay was first fully interpreted, very recently, by the brilliant work of Professor Bethe of Cornell. The plot is a bit complicated, and it will be well if we begin with a list of dramatis personne-that is, of the various sorts of atoms, and of those of their properties which concern the action:

The Lighter Atoms.

Name	$S_1 mbol$	Charge	Wass
Electron	e	1	0 00055
Neutron	n	0	1 00893
Hydrogen	H1	1	1 00813
Deuterium	112	1	2 01473
Helium	He3	2	3 01699
Helium	He	2	4 00386
Lithiuni	Li^a	3	6 01686
Luhium	L_1 ⁷	3	7.01818
Beryllium	Be	4	9.01504
Boron	B10	5	10 01631
Boron	B11	5	11 01292
Carbon	C12	6	12.00398
Carbon	Č13	6	13 00761
Vitrogen	NII	7	14 00750
Nitrogen	N15	7	15.00489
Oxygen	016	8	16 00000

The masses given in the last column are the values for the whole atom-to get that of the nucleus, subtract the mass of the number of electrons given in the third column; for example, a hydrogen nucleus (proton) has the mass 1 00758, and a helium nucleus (alpha particle) 4.00276. The various isotopes of the elements are listed separately. The more abundant ones are named in stalics We have now to fix our attention on the small decimal parts of the numbers in this last column. In a reaction between nuclei-whether they combine or break up-the main part of the mass is not altered-only the small "mass excess" above a whole number.1 We may, if we will, think of the whole numbers as representing in some way the "quantity of matter" (whatever that may mean) and the decimal parts the differences in the According to Bethe's Theory, the Most Notable Achievement of Theoretical Astrophysics of the Last Fifteen Years, It is Atomic Transformations

> By HENRY NORRIS RUSSELL, Ph.D. Chairman of the Department of Astronomy and Director of the Ob-servatory at Princeton University, Research Associate of the Mount Wilson Observatory of the Carnegus Institution of Washington

amounts of energy with which they are bound together into a unit. The tighter they are bound, the smaller, naturally, is the mass-excess.

It thus appears that the helium nucleus, and those of carbon and the following elements, represent configurations of low internal energy, while hydrogen is highest up on the scale (except for neutrons, which, as we pointed out last month, will be very short lived inside a star).

The transformation of hydrogen into heavier elements is therefore the main process to which we must look within the stars Four neutral hydrogen atoms have a mass 403252, which exceeds that of a behum atom by 0.02866, or one part in 141. This looks small, but if the Sun was made of hydrogen, and turned into behum, the energy corresponding to the loss of mass would keep it slinning at the present rate for 106 billion years. We have at last found an adequate source of stellar energy Other transformations would give much less, for example, to turn four behum atoms into one of oxygen (if possible) would diminish the mass by one part in 1040, and be but a tenth as effective.

WE may now-following Bethe-consider what is known about the various reactions between these atoms

In the first place, only hydrogen nuclei (protons or denterons) produce effects of importance. An alpha-particle has twice the charge of the proton, and so is more strongly repelled, and, having four times the mass, it moves but half as fast at the same temperature. It is therefore enormously less likely to "penetrate" another nucleus.

Secondly, most of the nuclei in the table can be penetrated by a proton, if hit hard enough, and transformed; but there is one great exception. Helium is invulnerable. If a proton entered an alpha-particle and fused with it, the resulting nucleus would have mass 5 and charge 3-it would be Li3. It might be, however, that as the proton entered, it knocked out a positive electron, reducing the charge by a unit; this would give He'. Neither of these has been found, experimentally; and there is very strong reason to believe that such nuclei are inherently unstable-not capable of independent existence for even the minute fraction of a second for which some radioactive nuclei endure. If two alpha-particles should penetrate one another, they would form Be" (charge 4, mass 8). This is now known to be unstable; it breaks up again into the two alpha-particles Hence helium, once formed, appears to be indestructible. Nothing more can happen to it. If hydrogen is the fuel of the stars, helium is the ashes.

Thirdly, the lighter nuclei, from deuterium to boron, react rather readily with protons. But, either at once or after two or three successive changes, the resulting products break up into helium, To take examples observed in the laboratory

Li1+H1 = 2He4; B11+H1=3Hc4 If hydrogen and light elements are originally present, these reactions will liberate a large amount of energy; but cach light nucleus, once caught, is used up, so that the process has a limit. With carbon. however, a new situation appears. As worked out hy Bethe, the first reaction is $C^{12} + H^1 = N^{14} + \gamma$

that is, a proton enters the carbon nucleus, producing a new nucleus of mass 13 and charge 7 (nitrogen). The energy corresponding to the loss in mass is liberated as a gamma-ray (y). The nucleus N13 has been produced artificially, and is radio-active, emitting a positive electron, and dropping back to charge 6.

N13 = C13 + e+

Another proton builds this up into or-

dinary nitrogen
C13+H1=N14+7 and still another into an isotope of oxygen

N14+H1=015+y This, again, is a known artificial radioactive element.

 $0^{15} = N^{15} + e^{+}$ We might expect N15 to be built up into

O16-common oxygen-but Bethe gives good reasons for supposing that, except in perhaps one case in ten thousand, the product of the next collision will break up into two pieces, according to the

Por many heavier atoms, such as Iron, there is a small "mass defect." but this does not con-cern us now

equation

 $N^{15}+H^{1}=C^{12}+He^{4}$

One of these is a helium nucleus—and the other is the carbon with which we started. We have here a regenerative process. The carbon is not used up, but re-cess. The carbon is not used up, but re-cess. The carbon is not used what wisap-peared, and been replaced by one alpha-particle. The energy corresponding to the loss of mass is illustrated in various ways, and as hiered cenergy of motion of the ejected positive electron or alpha-particle; but these will quickly be converted into energy of heat-motion in the gas.

The positive electrons, by the way, will not last long. They will meet negative electrons, and, in this case (unlike whole atoms) the two may annihilate one another—liberating still more energy.

Finally, the rates at which all these reactions occur increase very rapidly with the temperature—but, at a given temperature—but, at a given temperature and a given temperature and all amounts at a given temperature and density can be calculated in many cases from laboratory observations of the yield of the products under known conditions, and estimated in the others on the basis of a fairly extensive knowledge of the general properties of the nuclei.

Suppose now that we had a mass-equal to the Sun's, containing (like the Sun's) percent of hydrogen, and all sorts of other elements. If it started with a very large diameter, its central temperature would be low, and none of the nurlear reactions would work. It would have to contract to keep shining, and so grow hotter inside.

WHEN the central temperature reached about 300,000 degrees (according to Bethe) hydrogen and deuterium would begin to interact, and by the time it had reached 400,000 degrees this reaction would supply enough heat to keep the star shining. The contraction would then almost cease until the deuterium was used up (not entirely, because, as it became exhausted, the temperature would have to rise a little to get enough heat out of the diminishing supply). When it was gone, contraction would ensue until, at about 2,000,000 degrees, lithium became available as "fuel' called another halt. Beryllium would work at about 3,000,000 degrees, and the two isotopes of boron at five and nine. With all these possibilities, the star might keep going for a good while; but so far as we can determine from the study of the spectra of the Sun and the stars, all these light elements are rare; their total amount is but a very small fraction of the hydrogen.

When they were all gone, there would be more contraction till, at a temperature of 15,000,000 degrees, carbon began to be attacked. At first the carbon would be turned into nitrogen: but, at 18,000,000 degrees, this too would react. Bethe's cyclical process would then be in operation—the carbon would be regenerated, and act as a catalyst to turn more hydrogen into helium. This stage would continue so long as my hydrogen was left—that is, for very much longer than all the previous ones.

We should therefore expect to find the great majority of the stars in this situation—but how can we check this by observation? The test is very simple—the central temperature, calculated thus from

Hans Albrecht Bethe, professor of physics at Cornell University and originator of the notable theory

atomic theory, should agree with that de-

The rate of the carbon-chain reaction increases very rapidly with the temperature—about as its 18th power. Hence, in a star which radiated 100 times as much leat per unit of mass as the Sun does, the temperature would have to be only 14 percent higher (if the density were the same too). That is, most off the stars tool, and the same tool. That is, most off the stars should have central temperatures of about 20 million degrees.

Now it has long been recognized that the stars of the main sequence—the most important of all groups—lave all about the same internal temperature, and, when allowance is nude for the hydrogen present, the temperature comes out close to 20,000,000 degrees. Even the differences between the bright white stars at the top of the sequence and the smaller and cooler ones like the Sun are represented by the theory. Bethe gives the following comparison (central temperatures in millions of degrees):

Strius U Ophiuchi T Cresi 18.5 22 26 30 Theory 32 Observation 19 26 The theoretical values would be changed by a few percent by different assumptions as to the amounts of carbon and nitrogen present in the stars, and the observed values by different adopted "models" of internal density. But the conspicuous agreement could hardly be vitiated. Here we reach the climax of the drama. Previously we could calculate, from the general properties of atoms, that a star of given mass and hydrogen content should be of a certain brightness. Now, from the properties of atomic nuclei, we wan ean show that most stars of the given mass should also be of a certain diameter, and a corresponding surface temperature.

In other words, from the mere statement that there is a body having 330,000 times the Earth's mass, and containing 35 percent of hydrogen, we can predict that it will have the size, brightness and temperature of the Sun. We could do the same for Surius, and for innumerable other stars The Main Sequence is theoretically explained

This is the most notable achievement of theoretical astrophysics since the establishment of the relation between mass and luminosity, and deserves all the credit that can be given it.

Certain consequences of Bethe's theory may be briefly discussed in closing.

Nuclear reactions involving heavier atoms-for example, building up oxygen into fluorine-are quite possible, but they would work at an appreciable rate only at higher temperatures than the carbon cycle, and so would not have a chance to happen in the stars Bethe and Gamow have given a great deal of attention to the question whether side-reactions, which happen to only a small percentage of the nuclei in a star, may build up heavier atoms, but have found every road blocked. There is at present no explanation low such elements as sodium, alcium and iron can have been formed. We must assume that they are "older than the stars" and for the present let it go at that.

THE history of a star, after the carbon cycle is at work, appears to be fairly clear. As it gradually uses up its hydrogen, at must get brighter—and expand a little, to keep its central temperature from rising too rapidly. After a very long time (Bethe calculates 12 billion years for the Sun) the hydrogen will become exhausted, the star will once more contract and draw upon gravity. Stars of small mass will end up as white dwarfs; showed large mass will shrink still more.

Finally, the giant stars are not yet accounted for. Their central temperatures must be far too low to "turn on" the carnon cycle—unless they are built internally upon a very different model with very high central condensation. This may be true: or they may contain large quantities of light atoms, and be consuming these; or perhaps they draw upon some energy-liberating process which has not yet been duplicated in the laboratory. We must at the moment rest uncertain—and the students of the stars have still something to work out.—Princeton University Observatory, April 5, 1939.

Rubber's 'Little Brother'

AMERICANS have become so accustomed to newspaper headlines proclaiming another minor miracle in science that it requires an outstanding achievement nowadays to make them pause and take notice.

Such an achievement has come out of the laboratory of the oldest rubber company in the middle west where scenaries have brought into the world a synthetic material so closely akin to rubber that it is being called rubber's 'Intle brother' The new whistance is Konseal, and, siginfeantly, its wonders can be introduced to the world on the one-hundredth anniversary of the discovery. In Charles Goodygar over his Mas-achievets kitchen store, of the process for vulcanizing rublies.

Koroscal is not a synthetic rubber its scientific god-parents are careful to point out, for no true synthetic rubber exists

Purified basic ingredients of the new material. Limestone, coke and salt are so common that only factory conditions can limit production

in the world today, although there are other rubber substitutes. Scientists have been searching for decades for the secret of nature that would enable them to manufacture rubber cheaply in the test tube, but the quest has been catalogued with such "impossibles" as the photosopher's store. Vet Korosal, it is discovered to the control of the property of the photosopher's store. Vet Korosal, it is discovered to the photosopher's store. Vet Korosal, it is discovered to the photosopher's the photosopher's store. Vet Korosal, it is discovered to the photosopher's the photosopher's the photosopher's the photosopher's the photosopher's the photosopher's photos

This new chemical compound opens up a vast new field of uithly because it has proved its ability to operate in places where rubber never could perform It is adaptable to varied uses, and in a variety of forms ranging from the fire-resisting coating on power transmission cables to lining in hot acid tanks and the fine-

Rubber-Like Material... Koroseal... Made of Limestone, Coke, Salt... Superior to Rubber in Several Ways... Not Yet Adapted to Automobile Tires

By FLORIAN E. WOOD

textured clothing in milady's wardrobe Since natural rubber is an indispensable product in daily life, and, therefore. a vital commodity in war-time, the discovery of Koroscal is highly significant as nations rush ahead with armaments. In the United States, a number of rubber-like synthetics have been developed since the World War, but the total annual commercial consumption of the artificial products has amounted to only about 1 percent of that of rubber. Nevertheless, such scientific strides have been made with these synthetics that the price of one artificial rubber product has been lowered from \$1.05 to 65 cents a pound, while natural rubber hovers currently about the 15-cent mark

Some American chemists have been hold enough to predict, in the light of rapid developments in the synthetic rubber field, that the rubber industry could make the United States independent of the need for natural rubber in one year with a sizable expenditure for equipment to manufacture Koroseal and other synthetic, rubber-like products. They point out that it required much larger sums and many years longer to bring natural rubber to a point of wide utility.

Significantly, scientists point out that it would require an acre of rubber trees. 17.520,000 hours, or 2000 years, to pro duce the same amount of natural rubber which could be turned out synthetically in one hour by a laboratory only one acre in area. This fact alone dramatically illustrates the importance of any synthetic material which possesses qualities that would enable science and industry to substitute it in services where natural rubber long has functioned For in commercial use today, rubber is the vital sinew of more than 32,000 varied products, most of which are indispensable to every-day life.

MANY "first cousins" of rubber have bobbed up in the laboratory, but only in very recent years have products been discovered and developed which, in addition to having rubber-like physical

properties, are so chemically constituted that in many special cases they will outserve rubber. For example, acids that chew the life out of every metal except the "noble metals," and devour stone or glass with equal case, leave Koroseal unblemished. Oils that permeate the pores of many substances, including rubber, and cause them to swell, soften, and disintegrate, practice their wiles in vain on Koroscal. Oxygen, great leveller of flesh, wood, and iron, won't leave a smudge on its face: and in resistance to water, a duck's back is no better. by comparison.

Koroseal's sire is a corrosive gas and its dam a colorless flammable gas. The factor which gives Koroseal an edge over rubber is its immunity to ozone, rays of the sun, and oil—all deadly enemies of natural rubber. Howmies of natural rubber.

This elaborate gown, prize-winner at America's first Rubber Ball, was fashioned of Koroseal.

Of the mis-called "synthetic rubhers" commercially available today, only one is dealt with speciheally in the accompanying artub-. There are, in fact, three important synthetics in this class; the following paragraphs summarze their characteristics and detail the useto which industy is putting them.

Koroseal products are resistant to moisture oxygen, ozone, strong aids and alkalies, and most corosive chemicals. Typical applications are wire and cable unsulation and sheathing, textile roll covering tank lining, pipe covering, onaling for plating racks, themically-resistant tuding, impregnated fabrics.

Neoprene is used primarily hecause of its resistance (1) to swelling in oil and gasoline, (2) to crarking in santight, (3) to deterioration under oxidizing conditionand (4) to softening at fairly high temperatures. It finds application in cub pump gasoline hose, crude oil hose, distillate hose, automotive goods suth as gackets mud vibration iosulators, primting plates and tollers, oil resisting transmission and conveyor belts, oil resisting packing, and the like.

Thiokof product are noted for their resistance to solvents, lacquers, goodne, and oils; their resistance to smulght and come; and then low permeability to gases, Principal uses are lacquer hose, crude oil hose, ignition cault pump gasoline hose, ignition caller overrance, oil-prod extension code impregnated paper goskets, and priming places. The Education

ever, scientists still face sev eral problems in connection with Koroscal. There is, for example, the problem of resiliency, where Koroseal lacks characteristics of rubbet Then, too, while Koroscal can adapt itself to temperature ranges from minus 40 degrees, Fahrenbert, to plus 150, Fabrenheit, research experts hone to increase this range and to change some of its present characteristics so that it will maintain a more stable consistency under temperature changes,

The peculiar difficulty of Koroscal to react favorably ander wide variances of temperature makes it unadaptionle, at present, to automobilities, Likewise, it cannot function under conditions where abrasion is encountered at high temperatures, although at low temperatures Koroscal can withstand abrasion very

well. With the objective of effecting these improvements, a staff of 20 technical expets is at work in the laboratory of The B. F. Goodrich Company, where the synthetic was discovered, to overcome its disadvantages.

Korossal made its first commercial appearance quite insuspiciously to rid electro-plating of one of its greatest handcaps since that industry's inception. Some metal racks on which were suspended objects to be plated in electrometal than the products plated. Korossal's peculiar resistance to plating solutious made it highly satisfactory for insulating these reacks, it has found its way into the steel industry as a lining for pickling wats, and it is the only material so far dissovered that defies the bot acids which are used in the pickling of stainless.

The new material so nearly resembles rubber that it may be worked on rubber machinery

steel. Recently, petuloum engineers in the west discovered that the great underground network of pipes which transports oil many niles from field to reservoir was being destroyed by sales of the earth acting upon the metal. Koroseal came to the resour, supplying a pratective coating similar to the picking vat lining. Transparent Koroseal is superior to

any other flexible material in resisting the diffusion of certain toxic gases which unght he used in wartime. The psychological effect of a transparent Koroseal ages mask is said by scientists to lift the solidier's morale 100 percent. Another possible war use for Koroseal is its application to soldier's uniforma, by coating or impregnation, to prevent mustard gas wounds. During the World War, thousands of soldiers received life-time wounds from this vicious gas, one of the

most difficult to combat on the battlefield. Koroscal is three times more effective than rubber in resisting mustard gas.

It is evident that this new synthetic lias boundless possibilities in the field of transportation, communication, and heavy industry, as well as in countless varieties of products, including wearing apparel. It can be poured, molded, or cut, coated, a painted, impregnated, or laminated, it can be firmly attached to metal, fabric or even to natural rubber,

BECAUSE Koroscal can be made jelly-soft or hone-hard, it has an extreme range of utility. The soft form, Korogel, was one of the first products sold com mercially, it was found highly satisfactory for making flexible molds from which plaster reproductions of art objects could be turned out with great facil ity, Koroseal's indifference to oil has made it possible to create molded partfor hydraulic shock absorbers and for gaskets, cups, or plungers which must withstand oil or grease The laboratory has practically completed the develop ment of a form of Koroscal for use as a container material for liquids, such as acids and oils, which cannot otherwise be marketed without considerable pack aging expense.

Since it is waterproof, sun-resisting Since it is waterproof, sun-resisting departs of the control of the contr

Koroseal atter processing, as extruded tubing, and in film form

for sports, every-day wear, and for evening finery

Indeed, this child of the test tube takes its place alongside such notable discoveries in the rubber industry as vulcanization, acceleration, reclamation, the pneumatic automobile tire, the airplane tire, the airplane descer, and other marvels of this age of chemical transformation. And although the search for nature's secret has not ended, scientists proclaim that this wonder baby is destined to extend widely the field of usefulness of artificial rubber-like materials.

Relativity 20 Years

(Part Two)
The General Theory

MURNING to the general theory of relativity, whose most distinguishing feature is its theory of gravitation, we find a very different situation from the one described last month with regard to the special theory. While gen erally acclaimed as one of the most important achievements of modern thought, its restricted field of application has severed it from contact with the most vital advances of present-day physics. Although both theories have been the target of hosts of irresponsible fanaties, the aloofness of the general theory has made possible attacks on it by a few presumably responsible scientists-even

though it has, by and large, received general acceptance because of the few observational effects which is predicte, and general admiration as a monumental accomplishment of the human mind. In evaluating it we must be careful to seek the open way between the Seylla of blind a priori acceptance and the Charybdis of neglect engendered by the myope view of the more extreme pragmatic cults.

In developing the general relativity theory of gravitation, Finstein took his cue from the empirical fact that the mass of a body, which is a measure of its ability to resist change of motion, is at the same time a measure of its ability to attract other bodies. This equivalence of "inertial" and "gravitational" mass is now attributed to the fact that in the general theory they are but two different asperts of one and the same thing-which we may, with suntable caution, take as a measure of the "curvature" of the physical space-time continnum. This geometrization supplants the Newtonian law of

gravitation, to which it is equivalent in the first approximation, but its astronomical predictions differ from the classical ones in certain extremely minute dictails, the principal ones being the advance of the perihelion of Mercury, the bending of light passing the Sun, and the shift toward the red of light from massive bodies. In spite of the relative uniquificance of these effects in the boader exheme of things, and in part An Evaluation of the Achievements of the Special and General Theories of Relativity During the 20 Years which Have Elapsed since the First Direct Observational Test of the General Theory

By H. P. ROBERTSON, Ph.D.
Professor of Mathematical Physics, Princeton University

because of the difficulties encountered in verifying them, there has been an unfortunate tendency to magnify their importance as crucial experiments, ignoring the more fundamental and most accurately verified cornerstone of the theony the above-mentioned identity of gravitational and merital mass.

Professor Einstein seated in his confortable old reading chair in the study of his modest, old-tashioned home, smoking one of his pet pipes as he reads. Three walls of the study are lined from floor to ceiling with books and periodicals. The fourth is a large plate glass window

Even so, three three astronomical consequences have given a good account of themselves since their enunciation two decades ago, and in each case have lent weight to the theory, for even in those observations which fail to reveal decisively the predicted effects, the results are less discrepant with relativity than with classical theory. The question of the advance of Mercury's perihelion can now be answered in the affirmative more firmly than at the beginning of this period; its severest critics have never been able to establish their case against it, and the improved orbit announced by K. P. Williams of Indiana last year is completely consistent with the predicted advance. The bending of light from stars at the limb of the Sun, perhaps tech-

nically the most difficult of verification, seemed for a time reasonably established from the plates obtained during the 1919 and 1922 eclipses, which yield an average deviation but 2 percent greater than the value 1".75 predicted by the theory for a star seen just past the limb of the Sun. But Freundlich and collaborators in Potsdam, on working up plates obtained during the 1929 eclipse, were led to a deviation of 2".25 and, although an independent reduction made by Trumpler of Califorma led to the predicted value, the original authors attributed this to arbitrariness in the reduction of the observations. In any case, the evidence is clearly in favor of the Einstein effect as opposed to the smaller value of 0".87 expected on the Newtonian theory; future eclipse plates may be expected to yield a more definitive quantitative check on the theory.

The third test, the shift of spectral lines toward the red in light from massive bodies, is

so small in the case of the Sun—a shift of the order of one one-hundredth of an Angstrom—that its existence is most difficult to establish. St. John of Mt. Wilson announced tentatively in 1923 that the residuals, aiter allowing for known effects such as the Doppler shift, were more consistent with the relativistic than with the classical theory; such is also the conclusion of the recent excellent work of the English astronomer Ever-

AFTER

shed on the problem. An unexpected test of this effect was furnished by Adams of Mt. Wilson in 1925, when he found that the companion of Sirius, a white dwarf, showed a residual red-shift 30 times as great as that expected from the Sun. Now the mass of the star is known. from the orbit, to be about 85 percent of that of the Sun, and the theory of these stars indicates that its radius should be between 21/2 percent and 3 percent of the Sun's radius; the shift predicted by the theory for such a star is, to within the errors attendant upon such work, just that observed. This may be considered a most valuable indirect confirmation of the theory of relativity-or of the theory of dwarf stars, whichever is considered the more doubtful! It is often remarked that this effect is also a consequence of the photon theory of light, the shift being due to loss of energy by the light-quant in escaping from the gravitational field, this derivation is, however, dependent on the general theory of relativity, as it assumes the identity of inertial and gravitational mass for light,

WE turn now to the cosmological problem, and the speculative attempts to answer questions concerning the geometry and physics of the space time universe as a whole The general theory of relativity attributes local irregularities in the geometry—that is, local gravitational fields—to irregularities in the distribution of matter: thus the 4dimensional geometry of the neighborhood of the Sun is such as to cause a planet to pursue what we, with our traditional ways of thinking, would express as a curved orbit described under the action of the Sun's gravitational field. This raises the question of what the geometry of the observable universe might be if we were to ignore these irregularities due to the agglomeration of matter into stars or systems of stars-that is, what the worldgeometry would be if all matter were considered as more or less uniformly distributed in space. The first attempt to answer this question is that given by Einstein in 1918; on assuming that the mean density of all matter in the universe is a constant throughout space and for all time, he arrived at the view that space is closed-the 3-dimensional analogue of the 2-dimensional surface of a sphereand that, accordingly, the total amount of matter in the universe is finite. The curvature of space, which is measured by the inverse square of its radius, would depend, and in a sense be due to, the

total amount of the matter contained in the world. In order to obtain this solution. representing the world as on the whole static-the distance between any two nebulae remaining constant except for fluctuations which would iron out in the long run-it was necessary to introduce more or less arbitrarily a certain constant. The introduction of this "cosmological constant" λ is a freedom allowed by the form of the fundamental equations of the theory of gravitation, but one which is unfortunately subject to no direct observational check. Although on the hypothesis of the "Emstem universe" à cau be indirectly determined from the total amount of matter, this is an interpretation which is not valid in the more general solutions of the problem which are to be considered below

The great Dutch astronomcr de Sitter seized upon the possibility opened by the introduction of λ to consider a universe in which the curva-

ture is due entirely to the unknown constant, and in which the total amount of matter is so small as to have but a negligible effect on the curvature But, in attempting to apply these hypothetical models to the explanation of large-scale phenomena in the actual world, both met with little success. In the first place, a most surprising effect was slowly coming to light through observations on the spiral nebulae, those great systems of stars, analogous to our own Milky Way system, distributed more or less at random throughout the observable universe. For they were found, almost without exception, to be receding from our galaxy or, at least, their spectra exhibited a shift toward the red of exactly the same kind as that which would be caused by a motion of recession along the line of sight. And further, the more faint the nebula, and therefore presumably the more distant, the greater was the velocity of recession. This was a phenomenon utterly inexplicable in terms of the Einstein universe, and although it could be accounted for in terms of the de Sitter model the amount of matter contained in the nebulae was found to be far too great to be considered as having a negligible effect on the geometrical structure of the universe.

Under these circumstances it seemed most natural to seek an intermediate solution, which could explain the existence and nature of this recession, but in which the effect of the matter was adequately taken into account. A family of possible solutions—actually, as it turned out later, the most general—was found by the late

Prof R. C. Tolman, physical chemist, mathematical physicist and dean of the Graduate School at the California Institute of Technology, one of whose special interests in the world of science is relativistic cosmology

Russian mathematician A. Friedmann, in 1922, and has since been the subject of exhaustive investigations by Lemaître of Louvain, Tolman of Pasadena, the present author, and a host of others. Among the multitude of special cases contained in this most general solution were some in which \(\lambda \) was positive and space finite (at present the most favored), others in which A could be set equal to zero and space taken either as finite or Euclidean. and still others (including all those for which \(\lambda \) is negative) in which the "radius" of the universe oscillates between a fixed maximum value and a very small mlnimum. The principal problem was then the determination of just which of these models would best fit the actual observations-that is, which choice of A and the curvature would give a model which best reproduced the large-scale phenomena of the actual observable uni-Verse

THE observations which were avail-THE observations which all able for this selection, say in 1933, yielded two of the required empirical data-the red-shift constant and an estlmate of the density of smoothed-out matter. The former was obtained from the work of Hubble and Humason of Mt. Wilson, according to which the red-shift of nebulae increases 550 kilometers per second with every million parsecs of distance, and the second was obtained from Hubble's estimates of the mass of an average nebula and the mean distance between them. But unfortunately these two important results were not enough, for they alone were too weak to single out a unique solution—which accounts for the model sonsistent with these data with which we were bombarded at about this time. But all those solutions had one surprising feature in common, they all modested that the present to expansion could have gone on for at most a very few thousand million years, not much more than the age of the Earth as a obtained by studies on the radio-cartifying obtained by studies on the radio-cartifying

The Canon Georges Lensitre, of the University of Louvain, one of the first to study the red shift

of the oldest geological strate? Although such a limited time would be difficult to recurcile with most of the theories of stellar evolution, there were nevertheless other observations which seemed also to indicate a comparable age for the solar system and the galaxy, many astronomers accordingly reconciled themselves tentatively to his "Short time scale"

More recently another survey, again by Hubble, promised to supply the data needed to narrow down the selection of possible models. This consisted in counts of the number of nebulae in selected regions whose apparent magnitudes were less than certain limiting magnitudes, hve such counts, ranging from magnitudes 18.5 to 21.0, were obtained. These may be thought of as giving the number of nebulae within a certain limiting distance of the observer, A little reflection on the nature of the surface of a sphere will make it clear that, in the three-dimensional analogue under consideration, the law of merease of these numbers should theoretically depend on the curreture of space; if their dependence is sufficiently marked, it should be practicable to obtain the curvature from these observations. Now the rate of merease of nebplac with distance, from these data, is different from that in a Euclidean space, the discrepancies being so large that if they are due to the proposed effect, the curvature must be surprisingly large. In fact, so large that the only model which fits both it and the red-shift data has a most uncomfortably small "radius" (470,-000,000 light-years) and a still more limited time scale-less than a 1.000,000,000 years, no compelling way of reconciling this latter with the geological time scale has yet been suggested. But this is not the only trouble, for the mean density of matter in such a model exceeds that contuned as luminous matter in the nebulac by a thousand-fold and, although it is conceivable that the universe contains this much dark matter, we have as yet no independent justification for assum ing that it does,

TWO alternatives for escaping from these uncomfortable conclusions are at hand. First, the assumption of uniform density may not be a sufficiently valid approximation for the nebular counts, as relatively small fluctuations in the density of nebulae in the survey regions would be sufficient to account for the discrepancy without the introduction of such a marked curvative effect, this possibility has been suggested by Shapley of Harvard, who has recently published data in support of it from a survey of nebulae in the southern hemisphere Decision on this question must presumably await further data -we may hope that it can be decided one way or the other with the and of the 200 inch reflector now under construction at the California Institute of Technology The other possible way out is to seck some effect hitherto unnoticed perhaps to assume that the red-shift is due to a degradation of energy in light traveling great distances, and not to the effects of motion away from us. Although many such ad hoc explanations have been offered, it is contrary to respectable scientific methodology to accept any of them until they are supported by some independent verification

The search for a unified field theory, which will geometrize electromagnetism in a way analogous to that in which the general theory trents gravitation, has not been successful. The most promising of these was that of Weyl, at that time in Zurich, but it too had to be surrendered; his fundamental principle of "gange-invariance" has, however, been incorpotated into modern quantum theory, where it promises to be an important tool for a future quantum electrodynamics. It has been found possible to give a mathematically unified treatment of electricity and gravitation by the use of a fifth dimension. as in the theories of Kaluza of Gottingen, Klein of Stockholm, and Veblen and Einstein of the Institute for Advanced Study. but this has not in itself materially furthered the physical problem. No attempt has been made to review here the status of Milne's weird cosmological theory, nor of Eddington's unholy union of quantum and relativity theories; these theories have been attacked as representing a retion to the outmoded Aristotelian method in science—the attempt to derive natural law from a pitori principles. It would therefore seem that, although at least hatter claims to have solved many of the really outstanding problems of physics, the acceptance of the methods by which the solutions have been obtained would represent a backward step.

In conclusion, the past 20 years have seen the special theory of relativity more and more firmly established as one of the most important and useful fields of modern physics, without which much of the modern work on atomic and nuclear structure would have been materially curtailed, if not impossible. On the other hand, the general theory has had but little contact with the advancing front of phyical science, its theory of gravitation has been successful in the limited range of astronomical phenomena in which it differs from the Newtonian, but its most important achievement has been the estabshment of the identity of inertial and gravitational mass - an achievement which may be expected to grow in im-

Dr Edwin P. Hubble, Mount Wilson astronomer, who has contributed invaluable data on the red shift

portance with the advent of some adcquate theory of the ultimate constituents of matter, even though it may at the same time suffer radical modification. The rise or fall of its cosmological offshoot, the theory of the expanding universe, can be expected to have but little effect on the general theory; as long as the theory of gravitation is accepted, any attempt to approximate the real world in terms of a homogeneous background must utilize one of the models with which relativistic cosmology is concerned—even though it would constitute an awkward anticlimax if it turned out that the red-shift were due to some agency at present unknown rather than to the expansion, to which these models seem so admirably adapted!

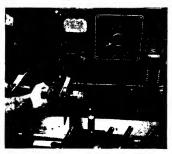

LOOKING FOR TROUBLE

Chromium plated gadgets and super-streamlining will sell an automodule, but to keep it wild without complicates a better-search who manufacturers maintain relationate inspection equipment. For example, at the right is shown one of the test complicated by one motors are maker. Steering knuckles are being magnetized prior to inspection for forging flaws. Ann annute flaw behaves like a magnet and is discovered when the knuckle is dupped into a superism of item blungs in kenson of

The illustration at the right shows an electrical thickness gage which is being used to "valiper" the engine walls. It contains coils which treate a magnetic field in the walls. The gage above measures life field strength; the scale has guidantions that indicate critiquely wall thickness in 64ths of an inch

One of the most as some and exacting jobs as that of fitting piston juris to piston. This is a function of the inspection department. The illustration at the left shows a hadroulle fixture for unserting pins. The gage multicates the pressure required to torce the jun into place. Tolerance limits are marked on the half; piston is repetched if too much to into hittle pressure is need

Not only is the importion department responsible for the materials and parts which point the automobile; it must chack all master parts. At the left is shown one of the most precise importion instruments; a cam checking facture. Here it is being used to check the contons of all surfaces of one of the master cans that are used to control one manufacture et a canstant production. Also, it is used in starting the production of a new model, for by means of this instrument it can be determined evently what part of any surface is inaccurate. The micrometer scales are graduated to 2000055 of an inch

THE GREAT AMERICAN RITE

WRITING in Manasata Medicine Medicine Medicine Medicine Medicine Sperimer, 1931, a dactor actually used this tate: "The American Rite—Tonslitectomy." He was in a mood of penitence. He held that the operation was rarely performed on adults without full and sufficient reason, because they were bug enough to fight back. But children were deprived of tonais the sufficient reason and the sufficient reason because they were bug enough to dight back.

Broadly speaking, said this physician, tonsis should be removed if they are greatly enlarged and amount to throat obstruction, if they are the seat of prolonged inflammatory disease; also if they can be proved to secrete possons—which brings up the theory of focal infection. Many children lose perfectly good tonsis which have swollen only temporarily while waging defensive warfare against infection, a congestion that can recur without permanent enlargement. The tonsis of infants should seldom or never be removed—that's what the Minnesoti doctor and, take it or leave it.

The British journal, The Medical Officer, has also commented on the recent fashion of tonsil removal In October, 1932, it remarked that a mere temporarily enlarged tonsil did not merit removal. and that it was impossible to divide tonsils into septic and nonseptic Indeed, it said, we really have no way of settling whether they should or should not be taken out. In October, 1938, it was even more emphatic. A Dr J. Alison Glover had just presented to the Royal Society of Medicine "strange facts" to speak for themselves, From 1929 to 1931 almost four percent of the children in Derbyshire had had their tonsils removed, but in 1933 the number had dropped to one tentli-yet there was no deterioration in child health. In two neighboring districts in London the respective removal rates were four percent and two tenths of one percent, without discernible differences in the health records of the children.

True, the idea that tonsils should go sa nol do use Hindu physicians have removed them for ages—at least as early es 1000 nc., but the known today, stemmed from articles by Dr. Frank Billings published between 1912 and 1914 In them, Billings accribed arthritis, nephritis, and later a wide variety of ailments to infected teeth in lus Laue Memorial Lecture in 1915, Dr. Billings defined a focus of infection as a circumseribed area of infection and the control of the circumseribed area of of the circumse

What Many Doctors Think About the Too Casual and Routine Removal of Tonsils . . . The Public is Partly to Blame . . . Are Tonsils Useful?

By T. SWANN HARDING

not nearby at all. As such foci of infection, he cited particularly tonsil abscess es, chronic simus infection, gallbladder and appendix infections, and bad teeth E. C. Rosenow and others further developed his theory mainly by work on animals

In 1938, Dr. David Riesman began to speculate as to whether painless, decayed teeth also might not cause ailments elsewhere in the body. Nor is there anything wrong with this theory, within strict scientific limitations. When it can be proved that a focus of infection definitely is causing disease elsewhere in the body. the focus-tonsil, teeth, gallbladder, appendix-should be removed. Often, however, the removal takes place in the absence of good evidence to indicate that the result will be good. And so many "preventive" removals do not act preventively. Too often the operation has not good, but bad, after-effects,

CONSIDER bad teeth. In The Journal of the American Medical Association as long ago an October, 1919, you will find an article by Dr. Walter C. Alvarez entitled "A Protest Against Reckless Extraction of Teeth" which is as true today as it was then. Too often removal of the teeth or of any other supposed focus of infection has no beneficial effect upon the patient's health. "In view of the fact that the most thorough removal of focal infections often falls to cure arthritis and other diseases, let us be more honest and conservative with our patients," wrote Dr. Alvarez.

In the same journal, in May, 1923, the same doctor wrote on "Lessons to Be Learned from the Results of Tonsillectomics in Adult Life." He demonstrated, after following up more than 300 cases, that the resultant improvement in health supposed to follow the tonsil amputation often did not occur. Those who had tonsillitis were almost always helped, but those who had no sore throat or tonsillitis were rarely pleased with the result of their operation. It paid best to remove tonsile for tonsillitis or sore throat. It paid less well to remove them for frequent colds. It did not pay at all to re-quent colds. It did not pay at all to re-quent colds. It did not pay at all to re-quent colds. It did not pay at all to re-

move them on general punciples, as a preventive measure in the hope of helping headaches, deafness, callarged neck glands, rheumatism, halitosis, and so on. In many such cases health became definitely worse after that operation than before. In two thirds of the rheumatism cases there was no benefit.

In many cases, Dr. Alvarez continued, repeated operations had been undergone because certain physicians attributed symptoms to tonsil fragments left behind by others. Some had had three and four operations with no benefit. Many had had tonails removed for most trivial reasons. Another man decided to have his tonsile out because of one mild attack of constipation. He nearly died of pneumonia following the operation, Two others succumbed to the temptation because they had physicians as personal friends who would operate gratis. Another had his removed because he blinked his eyes; he still blinked after his tonsils were subtracted. Another thought the operation would cure his insomna. As a whole, nearly one in ten victims of tonsillectomy had bad results.

Some nearly bled to death in the opcration or died of pneumonia afterward Some had recurrent bronchitis, difficulty in swallowing, odd feelings in the throat, loss in weight, nervous breakdowns, increased frequency of colds, sinusitis, ear noises, or no relief from the original symptoms leading to the operation.

It should be emphasized that, according to an editorial in our leading medical pournal in 1926, both tonsil operations and mass extractions of teeth ought be classified as major operations. Broncho-pneumonia and lung abacesses can and often do follow tonsillectonies under ether. Very severe and sometimes fatal complications have also followed an occasional booth extraction. Tonsillectomy under a local anesthetic is relatively asfe. In other words, these are operations that should be undertaken only when the indications clearly justify such drastic procedure.

In short, the entire literature on tonsillectomy is convincingly consistent in showing that too many tonsils are sacrificed and the expected beneficial results too rarely occur.

Go back to 1927. In The Journal of the American Medical Association for December 24, you will find Dr. Albert J. Welch giving a statistical report on 1000 pairs of tonsils excised. In nearly half the oases no benefit to health resulted. Bacterial studies were futile because any organism having access to the mouth-and that means myriads—can be shown to be present in the tonsils. Only four bad infective or malignant lesions were found in the lot. Only 70 showed ulceration.

In 1928, a Public Health Bulletin, No. 175, appeared and the work of Dr. Kaiser of Rochester was also being discussed. Kaiser found that tonsil removals did nothing to remedy rheumatism, chorea, or heart defects in children but did reduce sore throats and head colds. The Public Health Service bulletin indicated that tonsillectomy did not reduce the frequency of sore throat among children. But it added that the words "normal," "discased," and "enlarged," as applied to tonsils, were meaningless because so differently interpreted by different peo-

N the December, 1928, American Heart Journal you will find a report on 413 tonsillectomies which had no effect on rheumatic infection. Neither were they beneficial in heart disease

In the Archives of Internal Medicine for April, 1931, Dr. Ruhy L. Cunning-ham discussed "Normal, Absent, and Pathologic Tonsils in Young Women," making a most careful study of the entire literature on this subject. She showed that all sorts of unproved hypotheses were held on the basis of poorly controlled and interpreted clinical observations. Careful statistical studies were made of 12,530 white female students, one third each with normal, absent, or diseased tonsils. The incidence of measles, mumps, chickenpox, whooping cough, scarlet fever, diphtheria, pneumonia, pleurisy, chronic colds, chorea, appendicitis operations, mastoiditis, and nasal operations was the same among the normals as among those with diseased tonsils. The group with absent tonsils actually had a higher incidence of all illnesses and operations than did either the normal or pathologic groups. Indications were that the removal of tonsils had had little helpful effect.

"A review of the literature relative to the effect of the condition of the tonsils on general health reveals a great lack of accurate information on the effect of tonsillectomy, when one considers the number of operations that have been per-formed," said Dr. Cunningham. Opin-ions were widely variant. But, even at that time, there was a sharply growing sentiment against taking the tonalls out for preventive or prophylactic reasons. The trend of these investigations shows

an unvarying consistency. We shall note but two more of them. Glover and Wilson reported in The British Medical Journal in September, 1932, on the end results of removing tonsils and adenoids from adolescents and, in general, found that they did not justify the great number of such operations. The incidence of sore throat might thus be slightly diminished, but colds were just as frequent, otitis, mustoid disease, bronchitis, and pneumonia also. No one could claim that

A doctor must be a hero to fight off some who shop for operations

the operation helped in acute rheumatic or heart ailments. The conclusions of Dr. Cunningham (above) were considcred fully supported and "a large proportion of the tonsillectomies now done in children are unnecessary, entail some risk, and give little or no return.

Finally, in The American Journal of the Diseases of Children, for August 1932, will be found reports showing that the removal of the tonsils affects neither susceptibility to diphtheria nor the incidence of scarlet fever. Meanwhile there is always a possibility that the tonsils actually perform some useful function, as Dr. Ivor Griffiths of London suggested in The Lancet for September 25, 1937. In some cases, said Dr. Griffiths, treatment of the sinuses would give the relief expected from tonsil removal. Removal of tonsils does not improve cases of middle ear disease, nasal catarrh, or acute explosive snoring. He then propounded the theory that the function of the tonsils was to excrete into the pharynx certain organisms that pass into them from the sinuses via the lymphatic glands. Hence tonsils should never be removed for nasal catarrh, Various experiments on dogs were offered in evidence. Dyes did pass into the tonsils via the lymphatics. Moreover, Dr. Griffiths did not think the helpful results commonly attributed to tonsillectomy usually occurred as hopefully predicted. He found discharging ears and mastoid dis-ease in many of 5000 tonsil-less children. He held that many objectionable living

bacteria are routed to the tonsils to be excreted into the alimentary tract for destruction. Hence it appears probable that tonsils are of some use. They may not only perform regular lymphatic functions, but they have this special bacteria-destroying function also (such is this theory) because of their anatomical position. And, advertising to the contrary notwithstanding, it should be emphasized that germs swallowed are rapidly destroyed by the stomach acid and the intestinal juices. Infection via the oral route cannot so easily occur, nor is gargling a very effective preventive measure.

Despite all this mass of evidence, discarded teeth continue to rain into the dentist's garhage pail and discarded tonsils to make flames roar in the hospital incinerator.

What, then, may we conclude to be constructive with regard to tonsils?

An editorial in the Journal of Laboratory and Clinical Medicine for May, 1933, said essentially that doctors should not regard the discovery of infected tonsils as sufficient cause to neglect the rest of a complete physical examination. Bad tonsils are potential factors in producing generalized diseases and infections far from their site, but people should not be led to expect miracles from tonsillectomies.

The removal of tonsils does tend to decrease the recurrence of sore throat, but you can have sore throat without tonsils, and many do. Respiratory infections and most other ailments are about as frequent after as before the operation. Anyway, it takes about ten years fully to demonstrate benefit from the operation in case of serious ailments.

THE removal of tonsils under ether THE removal of which should be regarded as a major operation, always undertaken in the light of its possible hazards and never in the lack of complete justification. Laymen should stop shopping around among doctors, as so many of them do now, trying to persuade them to do an unnecessary tonsillectomy.

Undoubtedly the operation, when its need is properly indicated, can be very beneficial. It is frequently advisable in children but is rather rarely of real value to older people. It is doubtful whether the removal of a focus of infection has a particle of influence on dozens of diseases for which it is done. Practical help occurs oftenest in arthritis, but in case of older people this is too often like locking the barn 50 or 60 years after the horse was stolen.

A person having a lot of tonsillitis and sore throat gets definite benefit from the operation; a person with none gets none. That, according to one of the best informed doctors the writer knows, is the most important thing to remember in connection with tonsillectomy.

A MONTHLY DIGEST

THE SCREEN OF TELEVISION

THE heart of the television set, the Testeron' on which the image appears, as the rathodicary tube Within it is a mass of metals coated with similable chemicals which, when hearted, enti-electron particles are formed into a stream on heam by suitable chemicals.

Scaling-off a cathode-ray tube

tule and are projected to a Buonscent screen at the wide end of the rathorleray tule

Impunging of the electrons on the serven causes visible illumnation of the serven at the point of impact At any given instant there is only a single dot of high on the cathoderay serven. The beam sweeps across the serven at more than two miles a needing and serves to weave a television image. The cathoderay these now lenging produced for home television cinetiamment have a face, cathoderay these now lenging produced for dimater of 12 to 13 makes for the larger lengths, are could be produced and range in price from about \$35 for the small tubes to more than \$75 for the larger tubes.

Brearse of the high vaccious in validate by thise, there is a pressure over the entry thise, there is a pressure over the entre glass surface which mass into many tomes for the larger times. To withstand these trushing strain, the titles have glass walls areiaging about ½ of an indi-thek Alen, the titles are examined for weakness, prior to being need, in a device known as a polarisetope, which indicates the strength or weakures of any parts of the glass.

prise an intricate assembly of nickel cylinders, doffering plates, and a cathod. The cylinders serve to accelerate the electrons and to foun them into a sharp electron beam, to focus the beam on the fluorescent screen, and to increase or decrease the intensity

of the beam The assembly of metal and glass parts is mounted in a funnel shaped glass envelope and scaled in place, as shown on our front cover A glass tube permits pinning the air out of the glass envelope, this operation taking over two hours for the larger tubes While the pumping operation is being con ducted, the glass envelope is baked in an oven, which is part of the exhaust equipment, at a temperature of approximately 750 degrees, Fahrenhen. This baking drives off mosture which might otherwise remain inside the tube. Another precaution taken to climinate undesirable gases in the evacu ated tube is a bombardment of the metal parts, accomplished by slipping heavy coils, carrying high frequency current, about the neck of the cathode-ray tube, so that the metal parts are heated to incandescence through high frequency induction

The construction and assembly of the callude-ray tibe calls for exceptional accuracy in positioning and spacing the paris, since such details affect the quality of fursibel tibes. Also, the metal parts must be inhedded in the glass, which calls for great skill on the part of workers familiar with glass working.

MAKE-UP IN DEFENSE

IURID-WHITE "cosmetics" are used by some oil-well and petroleum-pipe-line workers. The oil-workers' facial adorament, however, is put on for defense

Petroleum geologists have discovered many oil fields beneath the waters of the Gulf of Mexico off the shores of Louisiana and Texas. Building a derick foundation under these difficult conditions made it necessary to us, crossored, water resistant timbers. One working on and around these timbers soon found that they caused painful facial inflamination and lurins. Pipedim workers, conting paper with a black water and corrision resistant, had the same trouble.

To protect themselves, they now danb their faces bliefally with a zine oxide preparation that gives them a bizarre appearance but says blisters and infectious

SMALL ARC WEIDER

A SMALL motor generator type are weld re, said to provide greater convenience and accuracy in welding because of a new self-indeating dual continuous current control, has been announced by The Lincoln

Electric Company Becames of its advanced features and moderate price, this unit is expected to within the application of welding in new fields such as garages, line and truck flert pairs sloops, sheet metal shops, maintenance departments of miph and paper mills, paint mills, cament plants, textile plants, gaplants, and smilar plants, as well as metal.

falurating shops, piping work, and so on The webler, known as the "A-150," hasboth job selector and current control calibrated and equipped with dials which in dicate the type of work and number of amperes for each and every setting. It is

For accuracy in welding

claimed that the development enables the welding operator to secure highest quality welds and highest possible welding speeds because he can vary both the slope of the volt-ampere crive and the amount of welding current independently and positively to sut every job encountered.

The unit is powered with a "Line-Weld," squirrel-eage, induction type moter for across-the-line starting. Connections are readily accessible for either 220 or 440 volts, 3 or 2-phase, 60 or 50 cycles as deared, the machine can be supplied for 550 volts or special voltages. Its current range is from 55 to 200 amorers.

SULFURIC

AIR and water, coming in contact with iron pyrites in roal mines, forms sulfurle acid amounting to about 2.802,000 tous per year, estimates the U.S. Public Health Service Sunce this water flows outward and pollutes streams, abandoned mines are being sealed up as fast as possible.

Engineering Costs

REDUCED

THE tremendous force excited by the extranson of concrete with the heat of the sim does costly damage to eiths and payments and presents a scrious problem to the engineers responsible for the establishment and maintenance of the moniments marking the lines of our enty streets.

An accompanying photograph is a view looking down into a manhole in the street and shows how the expanding pseement has moved toward the left, carrying with it the seast iron run that supports the manhole cover, and crushing the upper course of hereks

It frequently happens that the place for the engineer's monument at the intersection of the center lines of the streets coincides

Even though the pavement moves, reference points of this type remain effective

with what is also the desirable place for a manhole and the likelihood of movement of points set on a manhole cover or in the pavement is well illustrated.

The instability of a ference pounts in the other and with a fit which of the street is shown in a second photograph. The arrow underset the bend of a spake set in the earth at a catch basin to serve both as a reference pourt and look mank lutder pressure of expansion the curb has shifted more than arish to the right, shearing off the wall of the catch hasin, and has raised up nearly that are inches pointing the value of the spake both as a reference point and as a hench mark.

By an original method of ntilizing the brick structure of existing manholes, below the pavement, the engineers of the Los Angeles Bureau of Engineering have reduced the cost of maintenance and at the same time increased the stability of the system of points marking the street lines.

Four holes are d'rulled in the manhole wall and lead plings driven into them. Brass hooks are then serewed into the lead plugs in such a position that strings stretched between opposite hooks as shown in the illustration will intersect at the intersection of the street lines.

In practice, the manhole cover is lifted and strings or long rubber bands placed on the looks and the point of intersection used

as if it were on the surface.

Painting the hooks with liquid asphalt protects them from corrosion by gases that may be present in the manhole.—Edwin L. Stocking

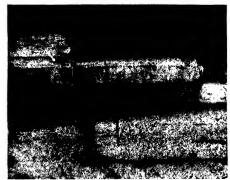

OXYGEN PRESERVES MILK

A NEW method of preserving liquid milk and nulk products, reported from Germany, consists of holding the milk at low temperature under oxygen pressure -- D, H K.

ACID-RESISTANT BOTTLE CLOSURE

THEIR aud-resisant transparent closure. Thas won for Merch & Company, Inc., hours in the Closure Group of the 1938 All-America Package Competition, sponsored by Vodern Packagen Magazine. This same closure also was selected for second award in the Scentific Group of the Third Annual Modern Plastics Competition, conducted by Modern Plastics Magazine.

This prize-winner utilizes an amber transpart polygon-shaped plastic cap, with a liner of impregnated glass cloth. The polystyrene cap is unaffected by the acid contents, and is always casy to remove and safe from leakage or breakage. It is used on an amber "Pour-Clean" bottle, which is named from the special pouring lip which is an in-

A serious problem for engineers: Expansion has moved a curb reference point

tegral part of the bottle opening and is covered by the acid-resistant closure

The prize-winning closure was molded by the Mack Molding Company from Bakeltic Polystyrene material, supplied by the Bakelite Corporation. The glass cloth for the cap liner is supplied by Owens Corning Fibrglas Corporation; the amber buttle by Anchor-Hocking Glass Corporation.

EXPANSION

BY high pressure hydrogenation, one and one fifth gallom of gasoline is being obtained in the United States from one gallon of oil. This is the highest yield yet attained by any process of treating petroleum.

PRE-TESTING THE AIRPLANE POWER PLANT

PLICHT testing a lugge flying hoat or a large landplane is a trieneadously expensive undertaking because of the powerful engines and the large crews required. Anything that can be done on the ground to shorten the flight tests is highly destable, and the Glenn L. Marrin Company has developed an engine test rigo to adview such an odd of the companies of the companies of the companies of the companies of the subble to determine the operating characteristics of the power plant months in advance of the trial flight.

The rig consust of a turntable on which is mounted a "mockup" of a proton of the arplane embracing a section of a wing and an engine in its nacelle. In the "observers' baleony" (to the right), located on a level with the engine, but shielded from it by a wall, are the instruments for recording temperature and pressure conditions throughout the fuel, oil, and cooling systems Our photograph has shown an elaborate portable rig for vibration study, which is an important part of power-plant tudy. The

propeller is, of course, included in the setup. The turntable makes testing possible with wind from various directions.

The use of the new rig speeds up delivery of a new model by as much as two months, reduces the hours needed for test flying by one third to one half, and fully justifies the somewhat heavy expense of building such a test installation.—A.

FLASHLIGHT PHOTOS 9000 FEET UNDER WATER

An appearus able to make flashlight picture 9000 feet heneath the surface of the water is the invention of Dr. Hofmann, as leading engineer of Munch. It is a deep-sea camera with which he has already conducted successful experiments in the depth-of Bodenee, or the Lake of Constance, as it is known to many American tourists. This invention as shortly to be subjected to further tests, this time 9000 feet below the level of the Tyrthenian Sea between Sardinia and the Inthus manufacture.

In recent times divers have penetrated farther and father into the depths of the ocean but after they reach a certain depth, the pre-sure of the water is so great that the stoutest diving suits are unable to offer resistance. Dr. Hofman's deep-sea camera have the advantage that no human being needs to accompany it not the ocean depths. It consists of a chamber nearly 18 inches in diameter, weighing rather more than a hindren properties of the properties of t

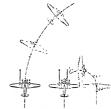

Increasing Flying Boat Maneuverability on the

WATER

ONLY small seaplanes have water rudders. The large flying boats have none, and the air rudder has but little effect when the flying boat is moving slowly on the

water. The maneuverability under such conditions is therefore very poor. To increase this maneuverability when using the present type of non-reversible pitch propellers, the pilot who wishes to turn to the right idles three engines of the four, and lets the left outboard engine pull him around. The turn is executed slowly and requires a great deal of room.

With the Curtiss electrically controlled propeller, it is now possible to reverse the pitch of the blades When the pitch is reversed, so is the thrust. The turn can then

Turning radii of flying boat on water with conventional propellers (left) and with reversible propellers

be executed much more rapidly, as indicated in the diagram, in which the arrows indicate the direction and relative magnitude of the thrust. It is obvious that, with appropriate reversal of pitch, a powerful turning movement can be applied. The pitch reversibility may also be employed in shortening the length of the run after algitum.—4. K.

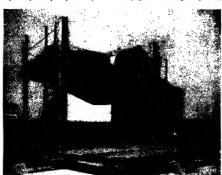

SAFE AIRPLANES

TENTATIVE specifications for private airplanes, intended to secure greater safety, have been susted by the Cuil Acronauties Authority. If these specifications—which are only tentative—are met, the Authority will allow the present dual instruction and solo flying time to be reduced appreciably in obtaining a nyate, pilot securificate.

obtaining a private pilot's certificate.
The sads history of the \$700 "diverve" airplane has made the industry a trifle skeptical
the new specifications. Airipace builders
say that their small craft are already reasonally safe, that aftery is a matter of care in
flying, and that radical changes in design
construction are say to defeat the very
construction are say to defeat the very
to the construction of the control of the control
attempt to increased safety. We shall not
attempt to increased safety. We shall not
attempt to increased safety. We shall not
attempt to increase the control of the control

attempt t

following quotation from the specifications:

*Landing and Taxying; (1) The simplane
shall be capable of being landed easily at
any speed between the minimum and at least
twee the minimum and shall tend to remain
on the ground after contact. (2) Fall application of brakes up to the point of skiddings
the tires throughout the entire landing run
shall be possible with no danger of nosing
over. (3) The landing gare shall be stable
in taxying and entirely free from ground
looping tendencies. The sirplane shall be

Airplane power plants are effectively pre-flight tested in this rie

easily accerable. (4) The airplane shall be capable of being landed over a 50-foot obstacle in a straight glide with no wind and brought to a stop within a horizontal distance of 500 feet. (5) The landing gers shall (a) landings having a vertical component of the velocity of 15 feet per second, and (b) straight glides to the ground in still air with the elevator control fall back, without overstressing any part of the airplane. (6) The airplane shall be able to tax in any direction and under complete control in winds up to 30 ms.h."

We believe that these requirements can be readily met by the use of the front nose wheel or "trucycle" landing gear; by bold use of flaps or air brakes; and by designing the shock absorber with a large travel and powerful shock absorbing qualities.

Other requirements call for adulity under varied conditions, impossibility of spinning under any conditions, and the provision of only two air controls, one governing the longitudinal attitude and the other for turning, both operated from the same control column.

Here we disagree with the spreifications of a surplane should be difficult to spin, but it is inconcrivable that it should never spin and a machine which cannot be epin voluntarily may also be hard to get out of the pin. Again, we do not believe that it is so difficult to learn to fly with three controls as to justify a surplement of the pin of the p

But it would be a great boon if the following "Minimum Field of View" were really made available to the pilot:

"The arplane while standing or taxying on level ground shall permit the plot an unobstructed level view straight ahead and through a lateral sweep of approximately 90 degrees to each side without moving from a natural comfortable position, and by reasonable movement the plot shall be able to see the ground within 20 feet ahead of the airplane."

With an inverted engine of narrow proportions, or a pusher machine, or just good design and plenty of window area, we think that our designers can come very close to securing this degree of vision.—A K.

MEASURING HORSEPOWER

IN arline operation, as much payload as possible must be carried on fast schedule, with the smallest fulc expenditure, and with the least wear on the engine. To check the two last items, the operator should have, at all times during a flight, an accurate record of the power developed by the engine. A number of ways exist for estimation

Diagram of a flying torque meter for measuring horsepower in flight

Stearman attack bomber, representative of advanced military practice

ing the power, but none of them is completely accurate. Mr. W. G. Lundquist, of the Wright A-ronautical Campany, in a paper presented before the Society of Automotive Engineers, advocates the use of a torque meter for this purpose. With such a meter, the power developed by the engine in fight can be determined with almost as much accuracy as in a test laboratory on the ground.

An example of the firms torque never An example of the firms torque never and the second of the

The use of a torque meter is but one example of the means which transport companies employ to check their operations

—A. K.

AIR CORPS EXPANSION

O UR readers are no doubt familiar, in general, with the program of Army Ar Corps. By July, 1941, the Ar Corps is to have a fighting force of 5500 to 6000 arthough a control of the property
In reading the various announcements, one is impressed first of all by the multiplicity of types available. Even towards the end of the World War, training, single-seater pursuit, day bomber, and heavy night bomber practically completed the classification. Now, further experience in various small wars, and careful testical attides, have led to a multiplicity of types, each adapted to one, or at most two, specialized purposes—four-engined flying fortresses, heavy bombers, single-engined pursuit, twin-en-

gined pursuits having speeds in the neighborhood of 400 miles an hour, troop carrying machines, interceptors to stop enemy bombers, multi-place fighters, and so on.

Both military designers and Corps tacticians are as a rule suspicious of airplanes which are to serve more than strictly limited purposes, because it has been found in the past that "all-purpose" machines serve all purposes badly. The construction of an "attack-homber" seems legitimate, however, for combining the high speed and powerful machine gun fire of the attack plane with the bomb equipment of a light bomber is logical enough. One of our photographs shows an attack bomber, the Stearman X-100, recently submitted in a competition in which North American and Glenn L. Martin were also among the participants. The X-100 is undoubtedly representative of the very latest practice. It is powered with two 1400-horsepower Pratt & Whitney R-2180 engines, the gross weight is approximately nine tons, the wing span is 65 feet, and the length is 52 feet. There is a crew of four to take care of navigation and machine gun and bomb compment. A feature of the new plane is the extreme vision afforded by the transparent panels which make up the entire forward portion. Since ar absolutely mooth skin is imperative at high speeds, flush type rivets are used over the entire surface of wings and body. In the design of the machine, an attempt has also been made to combine the ultimate in streamlining with the demands of rapid, large-scale production .- A. K.

STRAW FOR FUEL

RUSSIAN tests of straw as fuel in gas producers have yielded one kilowatt hour by burning three kilograms of straw. —D. H. K.

MACHINE CALCULATES TIMBER VOLUME IN FIVE SECONDS

A MACHINE which in five seconds gives the exact volume of a growing tree of any kind and any dimensions, and two other interesting instruments for timber assessments, have been built by a Swedish in-

The "trunk volume calculator," as the machine is called, has been constructed by a Swedish forestry technical expert, Capt. Alvar Drangel of Stockholm, and It has been

considered of such value that the Swedish government has helped finance manufacture and exploitation, It is a "nomo-mechanical calculating machine, equipped with certain mechanical devices through which a number of scales can be set in relation to cach other The machine is, practically speaking, an endless table system, which in five seconds solves an equation after five of its variables have been given exact values. For assessment of the cubic content of growing trees, the machine is thus set for the values of the trunk curvature, the class of bark, the taper percentage, the length of the trunk and, bually, the diameter of the tree at breast beight. The volume is then immediately obtained, exact to a ten thousandth of a rubic meter The machine, which has about the shape of an ordinary calculating machine, but is operated by dials instead of keys, is able to deliver no less than 8,000,000 volume figures

The two other instruments, constructed by the same inventor, are a "trink diameter registrator," working on the same principles as the first-mentioned machine and of about the same type, and a precision height measuring instrument, by means of which the height from the cut to any desired point on the trunk can be rapidly and correctly fixed The trunk diameter registrator is used for pre-calculation of the quantity of usable timher that can be obtained from a tree By means of it can be exactly fixed the top diameter in eighths of an meli within bark at a certain length from the cut or, the reverse, the log length at a certain desired top diameter - Holger Lundbergh

WORLD'S BEST LIGHTED FIELD FOR NIGHT BASEBALL

WHEN Comme Mack's Athletics and the Cleveland Indians inaugurated night baseball for the American League at Shibe Park, Philadelphia, on May 16, they played

on the best lighted sports field in the world Comprising 780 Westinghouse floodlights of 1500-wait capacity each, the new two-billou beam-candlepower lighting installation is of sufficient intensity to light a street 160

Two-billion candlepower makes this ball field the best lighted in the world. Below. One of the 1500-

inites long as brilliantly as Philadelphia s famous Broad Street; to provide light for more than 2000 homes, to make newspapers readable 175 miles from the light source, if the Boodlights were all concentrated in a single unit

"The Shibe Park infield is 20 times brighter than the average well-lighted office," actording to John Kilpatrick, lighting engineer. "It is several hundred times brighter than New York's Times Square on New Year's Eve."

There is no glare and resulting eyestrain for either spectators or players, Mr. Kilpatrick reported. This is due to the design of the floodlights and the unusual height at which they are placed. Too rows of lights in eight steel towers surrounding the park are 155 feet above the ground.

Six towers support targets on which are mounted 110 of the big 20-inch floodlights in 10 nerzontal rows of 11 lights each. Two others support 60 floodlights in five horizontal rows each contaming 12 lights.

Club officials announce that seven night

games will be played at Shibe Park this season by the Athletics, and seven by the Phillies It is also expected that the park will be used for night football games this fall.

MEASURING 2/100,000 OF

A MILLIMETER

A REMARKABLE measuring instrument, known as the "Microkator," which is capable of registering measurements down to 2/100,000 of a millimeter, has been invented by Hugo Abramson, Swedish engineer.

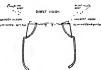

The principle applies a fretionless gear up to measuring instruments, and is remarkably simple. Its unit comprises, in the man, a thin strip of phospho-bronne, tweeted around its own hongrindinal aris, half arise to the strip of the strip

The inventor of this instrument, which is manufactured by the Swedish manufactured on the well known Johanson gage block and precision measuring instruments, the C. E. Johanson Company, of Edidstria, also has a number of other inventors in the precision measuring line to his studie, as a basic as a number of other inventors in the precision measuring line to his studie, as to example, the heatt heat indicator constructed by himself and his healther, Mr Abramon also has received the Gold Medal of the Swedish Academy for Engineering Research—Hidge Lindburgh

VISION CONCENTRATORS

The almost naturative for a pressure on extra me occasions to one his hands about his eyes the lietter to concentrate his vision in some scine or work before him. There is a debute principle involved in this action Eliminating inferret vision—or wide-angle vision—gives what is retinically called "ental fination"—secentially. Yimined vision." In specific seeing tasks, this is advantageous or, since objects in the periphery are abut vicinity in the contraction of the contraction of the which the attention is founded.

A simple device to attain this advantage has been developed by Frederick Saunders

and is being manufactured by the Columbia Protektosite Company. The invention came about as the result of Mr. Saunders' experimental use of two rolled-up programs at a moving picture show. Viewing the screen with them at his eyes started Mr. Saunders on a long study which resulted in the device called Concentrators. They literally congen-

A strikung example of a multiple electric motor installation. Not just one large motor or several smaller ones, but scores of individual units drive the many rolls on this run-out table at the new Sparrows Point. Maryland, bottstrip mill of the Bethichem Steel Company, Westinghouse made all the electrical equipment of this plant which turns out up to 2000 linear feet per minute of strip steel during long runs of tonings.

trate the sight and thus enable the user to concentrate more efficiently mentally

Concentrators look somewhat like ordinary spectacles, but they differ in having no lenses -unless the user needs sight correcting lenses-and in their patented features. To the outer eircumference of each eye piece there is molded a small opaque rim flange which projects forward and cuts down th angle of vision from side to side Projecting backward from the same rims, are shields which cut off all side light. The result is that all distracting side vision is completely eliminated. The effect is so marked that Dr Martin Grabau, former Harvard Uni versity physics professor, after testing and approving Concentrators, remarked that it was amazing how much could be accomplished so simply

phished so simply
Concentrators will be useful for students, stenographers, golfers and other sportsmen, theater-goers, and all those who must concentrate on work in hand.

GROWING TOBACCO WITH-

REPORTS from Italy state that tobacco leaves grafted on tomato plants grow with a total disappearance of necotine Leaves normally containing 2 to 2.5 percent income were used in the experiments and lost all their necotine content without having it appear in the leaves of the plant to which the graft was made—D. H. K.

"PULLMAN" FOR

TRUCKS are built these days to perform most any transportation job you care to name, but few are designed for a purpose as unusual as a fleet of eight recently ordered by the U. S. Bureau of Reclamation.

These are to carry thousands of giant salmon, 30, 40, or 50 at a time, alive and undamaged, to destinations they never would reach manded The fish will travel in 1000 gallons of Columbia River water, constantly acracted to supply the occupants with adequate oxygen, protected by insulation against conside temperatures ranging from 108 degrees down to 30 In trainst, the salmon compartment will be cooled gradually to prepare the occupants for the chill waters of Wenatcher River and Irclec Creek, Cracked ree, weighing 1800 pounds, is carried in a special compariment for this purpose.

Extraordinary precautions are being taken to keep the motoring side comfortable and unhurt. Every inside contour of the tanks is to be smoothed, and they are designed so as to fill to the brims, since the salmon must not be langed against the sides y slocking water. Specifications demand a 50-mile top speed with a gross lead of 25,000 pounds.
The job is an important one, affecting the luture of a great industry.

Up the Columbia River each year moves the greatest salmon run in the world, some three million fish, Chinook and Steelhead, bound for the headwaters to spawn and start the life of a new generation. The parent fish die but tiny yonigsters go down to the ocean to grow. Five years later, averaging 22 to 30 pounds apiece, these splendid salmon retrace their way upstream to their native waters.

A \$15,000,000 a year industry depends upon the continuance of this vast migration,
but its way now is disputed by power dame
built to harness the vast energy of the turbulent hurrying river. Millions have been
spent to build fish ladders to get them past
Bonneville Dam, but at Grand Coulee, 450
miles from the sea, the way is blocked.

The task given the eight fish "limousines" is to collect the asimon whose insute heads them to the streams above Grand Coulee, and carry them to other, sublocked inthiataries. It will not be an easy job From July to the end of September, the run will be at its peak, and fish trucks will have to be on the orall tile time employing the fish of the country of the cou

ALCOHOL ANTISEPTIC FOR WAR-WOUNDED

HOW warstorn Spain became the proving ground for a new type of alcohol anti-sepite vs revealed for the first time in Midstery Surgeon, official publication of the U.S. Association of Military Surgeon. Adding weight to the report is the fact that its author, Major S, Penez-Vasquez, M.D., was physician in charge of the famous Hospital de Carabineros in Madrid.

The new alcohol antiseptic which Dr. Perez-Va-quez found to be the "most satisfactory of any preparation in general use" may have even wider application in peace. He writes that, on war wounds of all types,

Special truck designed to carry giant salmon, alive

it not only controlled infection with less discomfort to the patient, but also speeded healing and shortened the period of hospitalization

"Even when . . . used several hours after injury, a quick drop in fever is observed, and within four days after beginning treatment, healthy granulation tissue appears. Much less operative surgery was required."

The new antiseptic—a mixture of ethyl alcohol, glycerine, thymol, phenol, and camphor—was evolved by Dr. Perez-Vasquez and liss associates in an effort to find a solution which could be used with simple irrigation in place of the cumbersome technique and specialized apparatus of the Carrell-Dakin method.

It was perfected, Dr. Perez-Vasquez states, after a careful trial of other approved and generally used antiseptics including rodine

and several proprietary products

The article in the Multary Surgeon gives
the formula and directions for compounding
the solution

A PROFESSOR'S SCIENTIFIC PIPE

WHEN science invades the sauctity of man's popular pastime of pipe smoking, the result is a highly-engineered job which offers convenience and satisfaction to the smoker. Latest evidence of this fact is

the scientifically-designed pipe invented and perfected by F. K. Kirsten, professor in the school of Aeronautical Engineering at the University of Washington.

An enthusastic pipe smoker himself, Prof Kirsten set about to apply engineering principles in developing a pipe that would elimmate the objectional features ordinarily associated with pipe smoking.

The Kristen pipe in based upon effective cooling of the molecular bounds on the undersuble oils and tare, which are in volatile form, are removed by condensation before creating the smoker's mouth. To obtain efficient cooling, a unique stem, or barrel, is used it is made of alumnium alloy and has a characteristic high their conductivity supplemented by an efficient flutted design which increases the rate of heat dissupation.

In order to allow ample time for the amoke to cool completely, the volume of the radiator has been precisely determined so that it holds the equivalent of the average smoker's puff, or from six to twelve cube centimeters. Because of the radiator's volume, the gases can remain in it for the duration of and the interval between puffs. Experiment has shown that this period is long enough for the commentations of the commentation of the commentat

plete cooling of the smoke and to permit the undesirable contents to condense.

The condensed tars and water vapor coler in a small radiust cap, also of aluminum alloy, at the lower end of the barrel—the lowest point of the pipe when in the smoking position. Their flow back into the bowl is prevented by a valve mechansum which is incorporated in the radiator cap. By giving the cap a right angle turn, the valve closes the bowl outlet, and the pipe can be turned to the bowl coulet, and the pipe can be turned to the cap are part to the bowl coulet, and the pipe can be turned to the cape a right cape to the couple to the cape and the cape and the cape and the cape to th

Left: The scientifically designed pipe has an aluminum stem. Abore: Each part of the pipe is designed to accurate engineering specifications. Parts are interchangeable. Right: The same principles have been applied to a cigarette holder

and none of its odors can escape. The radiator cap can readily be removed to empty the condensates.

The bowl of the Kirsten pipe is detachable, being held in place by a double-builted aluminum alloy screw which forms the bottom of the bowl. The farme permats the smoker to meterchange the bowl with any one of a sarrely of stuck shapes and size available. The mner walls of the bowl are alonged to give the most efficient combustion of the to-bacco, it was found that the most uniform burning was reflected by shaping the sales of the bowl so that they formed an angle of 38 degrees with the vertical.

An alumnum ramrod is attached to the make tube fitted in the mouthpiece and serves as an aid in cleaning the pipe by running a piece of tissue paper through the radiator, an action not unlike cleaning the

barrel of a gun.

The pipe is 10 to 50 percent lighter than the conventional design pipes.

The scientific principles of the Kirsten pipe have been carried a step further in the Kirsten cigarette holder which also cools (and cleans) the smoke through radiation from a finned aluminum alloy stem.

DIPHENYL SAVES PALES-TINE'S CITRUS INDUSTRY

I ONG distance shipping of Palestine's Lacitrus fruit crop is made possible by wrapping it in impregnated paper. Losses by spoilage are reduced by this method to

approximately 10 percent of their former value. Diphenyl is used to impregnate the wrapping paper and this in no way affects the odor, taste, or appearance of the fruit. This method may save the citrus fruit industry of Palestine by permitting the economical export of its product to remote markets in north Europe.—D. H. K.

SELF-ADHESIVE LABELS

SELF-ADHESIVE labels, manufactured by Avery Adhesives, coated on one side with a non-drying gum, will adhere to any smooth, hard surface without leaving any stain or gummy residue no matter how long they are in place. These Kum Klean labels can be used for marking glassware, silver, office supplies, pottery, china, toys, furniture, and other merchandise.

INSECTS versus WEEDS

A TINY Argentine moth has saved a training from being turned into desert by a predaction plant which was devouring more than 1000 acres a year, literally driving farmers out of their houses, and resisting attacks with liquid fire. The plant is the pricky pear, a species of certus common over the United States, Micros, and South America, and which is often grown as an ornamental in gardens.

Nearly a half century ago a few plants were introduced into Australia from North America, intended for flower gardens. The prickly pears found themselves in an earthly paradise where they could run wild will nothing to stop them. By 1925, they had

covered more than 60,000,000 acres in Ouernsland and New South Wales. Most of this had been good grazing and farming land. About balf of it was in the grip of a dense jungle of actuals from three to five feet high and so thick that it was impenetrable. The other half was covered by less dense growth, but was rendered nearly useless for sarreduter.

Just when the problem seemed unsolvable, salvation came in the form of the little Argentine moth. Australian entomologists had hunted all over the Americas for insects which might help get rid of the cactus. Many type specimens were studied in the collections of the Smithsonian Institution. The majority of them, it was found, did we real good. Their larvae ate the cactus, but the

plant was too tough to be killed by them. The Argentine moth, however, displayed life habits which admirably fitted it to rescue a continent.

The Australian entomologius tell of one stretch in Southwest Queensland where the prickly pear extended in a dense, almost continuous belief for 100 miles. A noth colony was planted in this neighborhood. A year later the entomologists were in despair. The niscets seemed to have done no good whatsower. Dut another 12 months and the whole jungle had simply collapsed. At least 90 per continuous productions of the production o

SULFANILAMIDE FOR SMALLPOX?

THE new drug sulfanilamide appears to have value in treating smallpox. Four cases in which it largely preented the eruption from the disease are reported in the Journal of the American Medical Association by Dr. Walter O. McCammon of Springfield, Kentucky.

Seven cases of smallpox recently came under the observation of Dr. McCammon He
used sulfamiliamde in treating four, and
there was only a slight cruption which soon
diasppeared. The patients were back at work
a week sooner than were the other three
cases which were treated symptomatically
and in which the typical cruption of smallpox
develoned.

In an editorial, the medical journal points out that no conclusions as to the value of sulfanilamide in preventing deaths from smallpox can be drawn from such a small number of cases

Although smallpox is increasing (there were 14,355 cases reported last year) the disease is now mild —Science Service

SEED GERMINATION WITH

NATURE'S way with seeds has always been hard to figure out—a hit-and-miss proposition largely based on guesswork. But the Peppard and the Rudy-Patrick Seed Companies of Kansas City, Missouri, have

Below: The air-conditioned unit for seed germination and, right, shelves on which seeds are placed

Gold in an automobile factory may seem incongruous, yet in the Rouse plant of the Ford More Car Company it does a "bloover," but of expediting the drying of enamels with which motor-eer parts are factored. (See a Cartelling the drying of enamels with which motor-eer parts are food. (See the control of the May, 1939, page 225.) This striking photograph shows one of the tunnels through which bodies are drawn, after painting, to be dried rapidly by the infrared rays from a battery of lamps. These lamps are backed by reflectors, the surfaces of which are gold plated, since it has been found that such a surface most efficiently concentrates the desired rays on the automobile body.

eliminated the guesswork and reduced the whole process to a science. They employ the use of seed germination boxes to test the growing ability of all varieties of field grasses and garden seed. In this way, Mother Nature's future whims are accurately prognosticated.

A given number of seeds from any one lot is placed on moist blotting paper and inserted in the germinating box. Within the box, it is imperative to hold the relative humidity at 90 percent and to maintain tem-

peratures which correspond as nearly as possible to the temperatures to which the seeds would be exposed in the fields during their planting or sprouting period. This temperature, of course, varies during the 24-hour daily cycle. Therefore, in the germinator, varying temperatures are maintained—name ly 68 degrees for 16 hours simulating the night, and 85 degrees during the eight hours

erresponding to the aunlight cycle.

Of course, there are aceds which must be

planted the first thing in the spring, such as radules, lettuce, alfalfs, and clovers. These do not require as much heat to protut and, therefore, are placed in one compartment of the compartment of 86 degrees. It is for the reason that each germandor is constructed with two compartment—one equipped only with refrigeration and the other with both refrigeration and an electric airly heater.

The Creamery Package Manufacturing Company of Chicago, through its Kansas City office, furnished these Trane germinatlag units.

shock treatment for insanity in a small series of cases were reported by Drs. H. E. Him-wich, F. A. D. Alexander, Basile Lipetz, and J. F. Fazekas, of Albany, New York, Medical College and Union University.

The new treatment achieves its effect by the same mechanism as the drastic insulin and metrazol shock treatments. This is by decreasing the metabolic activity of the brain. The nitrogen inhalation treatment, however, is easier to give than insulin shock and does not produce the fearful convulsions of metrazol treatments which are dreaded by both patients and physicians.

With the new treatment, patients breathe nitrogen long enough to deprive the brain of its oxygen supply for about five minutes These treatments are given three times a week for a period of about three months.

Cutting down the oxygen supply to the brain reduces its inetabolic activity. Metrazol does the same thing by temporarily ar resting breathing movements. Insulin shock does it by depleting the sugar supply to the brain, without which the brain cannot use orveen

The fact that metrazol and menhashock treatments both produced this effect of decreased metabolic activity was discovered a year ago by a University of Toronto research team under the leadership of Sir Frederick Banting and Dr & Edward Hall. At that time Dr. Hall predicted that neither insulin nor metrazol would be the last word in treat ment of schrophrenia and that a better and less severe remedy would be found to replace them The nitrogen inhalation treatment seems now to be that remedy ... Science Service

ALLMINUM IS SOURTED

AllONG the manufacturing operations performed on aliminium alloys, none is more interesting and speciacular than the impact extrusion process. By this method, a small be out-shaped slug of aluminum is transformed in the twinkling of an eye into a tooth paste tube, a flashlight case, or any one of several hundred commonplace containers and shapes

The moving head of an impact extrusion press is fitted with a punch or hammer which is slightly smaller in cross-sectional dimensions than the stationary die The slug of aluminum is placed on the die, the hammer strikes the slug, and the high pressure forces the aluminum slug to "flow" up past the clearance between die and hammer, thus forming a collapsible tube or any other shape determined by the die The metal is literally "squirted" into the desired shape.

Pieces and containers of various si shapes, and intricacy of design can be formed

A slug of aluminum is in the

The aluminum is squirted

extrusion process. Many parts ordinarily made by drawing, spinning, stamping or turning can be produced to advantage by this method. The chief advantages to be obtained by adopting this process are closed diamentonal tolerance, a high degree of uniformity in parts, and surprisingly low production costs.

By the nature of the impact extrusion process, the metal is strain-hardened, devel-

. . and a formed tube results

oping its strength and stiffness. Thermal freatment may be used to anneal the finished product for the softness necessary in collapsble tubes or the parts may be given even higher strength by controlled heat treatment. Thus, various properties are at the option of the designer

There are almost no limitations on the shapes of impact extrasions. Symmetrical and basically cylindrical forms are the bessured to this process, but square, outh, revtangular, and asymmetrical parts can be made rapidly and a low unit con. The wall blickness of parts can be varied from thirds with a point's of stress and strain to this natural light weight of aluminum is added the advantage of less griefs where on aerded

BEWARE! TICKS CARRY SPOTTED FEVER

CONSIDER all ticks dangerous, advises the U. S. Public Health Service, even though only one in 300 of the eight-legged pests is capable of transmitting spotted feeer, in the most heavily infected areas.

Although the exceedingly dangerous tickborne disease was first found in the west, whence its name of Rocky Mountain spotted fever, it is now known to exist eastward to the Atlanic, as far north as Massachusetts, and as far south as Georgia.

If you live where ticks abound, or if your dog brings them to the house after cruising in the brinsh, better examine yourself all over at least once a day off you find a tick has taken hold, remove him with a pair of

WHERE SCIENCE ENDS HOSPITALITY BEGINS

The Waldorf, for example, is a magnificent scientific achievement, not only dependent on science when it was built, but continuously dependent on many sciences for the efficiency of its operation.

But every man of scientific turn of mind knows what we mean when we say that hospitality, in his own home no less than in the Waldorf, is something warm, hymg and human that survives scientific detachment.

And it is that ability to preserve the human touch, in spite of all our clockwork schedules and efficiency, that gives the Waldorf its unique reputation for maintaining close, cordial and communicable contacts with its patrons.

Besides, this year, when you come to New York, you'll get so much science at THE FAIR, that it'll be a genuine relief each day to return to the hospitality of The Waldorf-Astoria!

tweezers or a small piece of cotton or papers being careful not to crush it. Tick "juice" can be very dangerous.

neeng caretin not or was it. Ites yuce can be very dangerous.
Drop the tick in kerosene or gasoline, to kill it. Swah the bitten spot with iodine, and dip your fingers and the forceps in alcohol or wash them thoroughly, the Public Health Service advises. It is highly advisable also to "de-tick" your dog at frequent intervals, with the same precedents.

INKLESS RECORDING

INSTRUMENTS

CONTINUOUS accurate operation for 30 days without attention, at temperatures as low as —10 degrees. Fahrenheit, and as high as 120 degrees, Fahrenheit, is made possible by the new Type CF1 line of inkless recording single- and double-range A.C. ameters and volumiters just announced by

the General Electric Company. The units are in the low-price range and are particularly well suited for voltage surveys, complaint investigations, and elecking circuit load conditions. The inkless mechanism, which uses a typewriter tibbon to make the record by a series of dots, results in greater simplicity, mail size, and light weight. There is no inkwell to clean, no pen to start, and nothing to freeze in cold weather. A cast aluminum alloy case protects the mechanism and forwhile expended to the weather. Although they are portable, the new instruments may be wall or pole-comment.

FLAMEPROOF FABRICS

FACTORY PRECISION

DON'T believe it if someone tells you that E. E. Burger, shown in an accompanying illustration, is sightling his bow and arrow for a bull'scyc shot at a target. The bull'scyc at which he is "aiming" is the measurement of any difference between the

Determining expansion coefficients

expansion coefficients of metal and glass. In the manufacture of vacuum tubes, insulators, and other electrical products, metal and glass must be sealed together to withstand varying temperatures, and it is through this tele-scopic "sight" that Mr. Burger determines expansions as small as ten milliontlis of an inch in the Research Laboratory of the General Electric Company

WELDED HACK SAW BLADES

HIGH efficiency is the claim of the Arm-strong-Blum Manufacturing Company for its Marvel high-speed-edge liack saw blades They are manufactured by uniting a high-speed steel tooth edge with a supporting body of chromium vanadium steel. The two parts are integrally welded by a patented electric welding process.

It is claimed that the high-speed steel edge provides all the fast-cutting and longwearing qualities of good cutting tools, while the body of chromium vanadium steel contributes exceptional strength.

ELECTROPLATING WITH A Review

SMALL repair shops and home workshops can now have their own electroplating equipment. An inexpensive kit recently put on the market by the Rapid Plating Process Inc., enables the shop or home user without previous experience to electroplate individual articles or worn spots on various ob-

The plating is done with a specially designed brush through which an electric current passes. Only one or two dry cells are required. The plating compound is of a jelly-like consistency and contains, in a highly concentrated form, the metal to be deposited This compound adheres to the surface being plated without spilling or running. Objects even in overhead positions may be plated without dismantling or loss of time from

It is claimed that the quality and permanency of the platings are equal to com-mercial platings, thickness for thickness. Nickel coatings of 1½ to 2 ten-thousandths can be successfully deposited with a com-

EVERY important discovery relating to mind power, sound thinking and cause and effect, as applied to self-advancement, was known centuries ago, before the masses could read and write. Much has been written about the wise men of old. A popular fallacy has it that their secrets of personal power and suc-cessful living were lost to the world. Knowledge of nature's laws, accumulat-

ed through the ages, is never lost. At times the great truths possessed by the sages were hidden from unacrupulous men in high places, but never destroyed. Why Were Their Secrets Closely Guarded?

Only recently, as time is measured; not Only recently, as time is measured; not more than twenty generations ago, less than 1/100th of 1% of the earth's people were thought capable of receiving basic knowledge about the laws of life, for it is an elementary truism that knowledge is power and that power cannot be entrusted to the ignorant and the unworthy.

Wisdom is not readily attainable by the general public; nor recognized when right within reach. The average person absorbs a multitude of details about things, but goes through life without ever knowing where and how to acquire mastery of the fundamentals of the inner mind—that mysterious allent compilies. mind—that mysterious allent something which "whispers" to you from within.

Fundamental Laws of Nature

Your habits, accomplianments and wear-nesses are the effects of causes. Your thoughts and actions are governed by fundamental laws. Example: The law of compensation is as fundamental as the laws of breathing, eating

and sleeping. All fixed laws of nature are as fascinating to study as they are vital to understand for success in life.

You can learn to find and follow every basic law of life. You can begin at any time to discover a whole new world of interesting truths. You can start at once interesting truths. You can start at once to awaken your inner powers of self-understanding a n d self-advancement. You can learn from one of the world's oldest institutions, first known in Amerlea in 1694. Enjoying the high regard of hundreds of leaders, thinkers and teachers, the order is known as the Rosicrucian Brotherhood. Its complete name is the "Ancient and Mystical Order Rosse Crucis," abbreviated by the initials "AMORC." The teachings of the Order are not sold, for it is not a commercial organization, nor is it a religious sect. It is a non-profit fraternity, a brotherhood in the true sense.

Not For General Distribution

Sincere men and women, in search of the truth—those who wish to fit in with the ways of the world—are invited to the ways of the world—are invited to write for complimentary copy of the sealed booklet, "The Secret Heritage." sealed booklet, "The Secret Heritage." It tells how to contact the librarian of the archives of AMORC for this rare knowledge. This booklet is not intended for general distribution; nor is it sent without request. It is therefore suggested that you write for your copy to the Serble whose address is given in the coupon. The initial step is for you to take.

Experimenters - Schools - Field Workers

An Accurate Balance at a Price Within the Reach of All

Sensitive to 2/50 gram Weighs up to 100 grams Compact-No loose parts Modern, durable construction Small convenient size Handsome streamline design Now permissible for auxiliary use in drug stores (N. Y. C. Serial B17.)

Never before a balance with all these exceptional features!

Finest Quality - Made of tested materials its Finct Quality - Vade of tested materials its construction will appear to laboratories stepting the best equipment. The Bakettle cup I-manffected by practically any substance that can come in contact with it the tool steel knife edge and again bearing will give long life and accuracy.

for any accountry—Weighs to one decimal point farther than the usual tow-priest country wales and serves nearly ever labora toy purpose short of precise analysis. The capacity of 100 grams is ample tor the delicate

weighings made in the usual course of leaching organic synthesis experimental work, compounding pholographic work etc.

Conject Convenient - Does not monopoliz laboratory table. Placed on the desk of bors technical executive it will soon bee indispensable. his small size makes it possible to cours it on hispection and testing trips at a distance from the laboratory. It is shall enough to be carried ander the ann or in an overcourt.

PERMO LIFETIME BINDER It holds a year's issues

SO MANY readers, preserve their cupies year after year and have asked for binders that, after thorough investigation of binders, the editors of Scientific American found a type that is most satisfactory, consolering cost, ease of handling, and durability. It blods a full vear's sauces (12); has an efficient patented lock; is strong and durabile; and is covered to a rich, pebblict of the latteries the beautifully stamped in gold. Magazines are bound in with a samp and are held possively in place, no punching necessary. In ordering, state what year (1998, 1993, rev.) is to be sampled in gold on the backhone

Each \$1.50 postpaid in continental U. S. (\$2.00 postpaid elsewhere) For Sale by SCIENTIFIC AMERICAN, 24 West 40th Street, New York paratively few brush strokes. Cadmium 2 to 4 ten-thousandths and silver 1 to 10 tenthousandths can be deposited, depending upon the time expended in the operation. Other metals which can be plated by this method are gold, copper, tin, and zinc.

The process is not designed to replace the commercial method of electroplating but rather to supplement it. The brush method is particularly useful for miscellaneous small tohs and for touching up small areas which are not subject to heavy wear,

ICE

APPROXIMATELY 15 million tons of ire-enough to make 240 billion average-size cubes-are required annually by the American railroads to keep freight and passengers cool. The great bulk of ice purchased or manufactured by the railroads and refrigerator car companies-nearly 13 million tons of it -goes in what have become known as "America's rolling refrigerators.

SOUEAKING RUBBER

THE problem of the squeaking rubber mounted spring shackle is an annoying one for motorists. Oil should not he used as a lubricant because of possible softening of the rubber, and brake fluid affords, at best, only a temporary remedy A satisfactory lubricant is made of colloidal graphite in glycerin and water, reports B II Porter, of Acheson Colloid Corporation Glycerin has desirable characteristics as a rubber lubricant and it increases the retention of the graphite by the lubricated parts. The water acts as a carrier and soon evaporates.

CORN COB LIGNIN SOFTENS CITY WATER

N their search for some practical use for IN their scarch for some products lignin, one of the principal waste products of the country, chemists have discovered that recovered lignin is more effective in treating hard water containing iron than commercial compounds now in use.

At the Agricultural By-Products Laboratory, Ames, Iowa, chemists of the U. S. Department of Agriculture treated hard city water, hard well water, and water containing added iron with lignin prepared from corn cobs and found this material to be effective as an iron-removal agent.

Supplies of lignin are inexpensive because they are almost limitless. Roughly, one fourth of all wood plants, meluding trees, is ligmin. As a waste product of wood pulp mills, where its disposal pollutes streams, it amounts to about 1,500,000 dry-weight-tons each year. At least six million tons a year is available from corn stalks and an equal quantity from wheat straw. Other extensive supplies are cottonseed hulls and sugar cane bagasse-the fiber remaining after the juice has been squeezed from it

In treating water that contained about 36 parts per million of iron with 500 parts per million of lignin, the iron content was reduced to an average of about two tenths of one part per million. The lignin was recovered and used again up to 10 times with no appreciable lessening of efficiency. The same

amount of an inorganic compound commonly in use reduced an identical iron content to only one and one half parts per million for the first six times it was used and thereafter rapidly lost its ability to remove the iron. The cheaper lignin powder not only removes more iron, but can be recovered and used more times.

Many cities may find it possible to use the lignin treatment with existing water filtra-tion plants by adding the recovered lignin to the water in the mixing and sedimentation tanks, or applying it as the water enters the moval

REVOLVING MULTIPLE-SCALES FOR METERS

ON the measuring instruments of the present day with several measuring ranges, it is necessary to multiply the results by a given factor which has a different magmtude for each measuring range These calculations not only entail waste of time, but they are a source of possible errors, and this, of course, means that they may constitute an

Above: Flexible multiple scale for meters, Belou Several rows of numbers on a conventional meter scale

element of danger for apparatus through which current flows. The difficulties are peculiarly serious in the case of several scales with varying characteristics.

The elimination of all calculating work, when using electric measuring instruments, can be made possible by introducing suit-ably divided and numbered divisions into the scale-field for each measuring range; on the other hand, it must not be necessary that a measuring range represent a given multiple of another range. This problem has been solved by the Toroid Multiple Scale. A rope pull, or toothed-wheel, coupling between measuring-range selector and multiple scale effects a positive change-over of the scale, along with the change-over of the measuring range, with the result that all risk of con fusion is climinated.

One of our illustrations shows the construction of the new revolving multiple-scale. A flexible roller, preferably a seamless foldtube in spring-bronze, is arranged to revolve on an axle which is curved to correspond with the form of the scale as it must appear behind the window of the case. It is coupled

with the measuring range selector which is constructed in the form of a rotary switch. Surrounding the flexible roller, an elastic sheathing in either cylindrical or prismatic form is firmly connected with the fold-tube, and on this the numerals or divisions are marked. Thanks to its unique construction, the fold-tube has been found quite torsionproof. It can be driven from one side, without twisting and there will, consequently, be no distortion of the divisions. The cylindrical revolving body is used when several rows of numerals must be interchangeable, while the prismatic form will be selected when not only numerals but also complete divisions must be changed

INVENTORS KEEP AFTER AUTO IMPROVEMENTS

NE in five of the 43,000 paients granted by the United States during 1938 had an automotive application

A total of 8268 of the patents granted re-lated to the motor vehicle in some fashion Not all affected the incchanical or exterior design of the car itself, many dealing with manufacture and repair, with parts, accessories, lubricants, fuels, as well as special machines and processes usable in car pro-

Of these, only 349 were assued to automobile manufacturing companies. The automo tive patents represented an increase of 1004 over the number granted in 1937, while the total volume of all patents granted was only 271 above the 1937 total

RUBBER PAINT

A PAINT containing a rubber hydro-carbon is said to be especially suitable for chemical laboratories because it is not only decorative but also resistant to acids, alkalies, fumes, and moisture, according to the Fisher Scientific Company Other claims are that the paint will not crack or peel at temperatures up to 350 degrees, Fahrenliest, and that it can be applied to wood, metal, plaster, concrete, or brick Plicote, as the paint is known, is available in ten colors and white

COMPOUNDED WOOD IS NEW MILLING ADVANCE

THE old practice of veneering furniture, which turned out a mahogany table for five dollars, is back in a new and much more fundamentally important form.

Compounding wood, as the process of veneering is known to the trade, is now turning to the new field of making wooden beams which have all the uniformity of characteristics of steel and other metals Do you wish a wood with a given density, a given elastic strength and other properties Compounded wood is the answer and each time you place an order with the mills it

Comes through the same, time after time.
Wood unsuted for many construction
purposes becomes the core of the plank and laminated layers aupply the exterior. The proportions of each are varied so that the same characteristics can be repeated at will.

In part, the use of phenolic resins as the gluing agent in the finished board is the difference between older veneer panels and the new beams of technologic mill working. The various layers of wood are arranged in

Are You

putting your spare time to good advantage?

one of the many who are seeking a new field to en-

seeking a means to save money wherever possible?

If you are, here is a practical solution to your problem.

HOPKINS' CYCLOPEDIA OF **FORMULAS**

Is the foundation for the beginning of a fascinating hobby; the groundwork on which to build a practical knowledge of useful chemical facts.

Is the foundation for hundreds of suggestions for those who are seeking salable articles which can be manufactured at home profitably on a small scale.

IF you want to save money on wines and liquors; your dyes, inks, polishes, soaps, paints and varnishes, adhesives, antiseptics, bleaches, cosmetics, etc.

You can profitably make them from the 15000 formulas contained in the 1077 pages of

HOPKINS'

Cyclopedia of Formulas \$5.50 postpaid (domestic)

books," dried, coated with the resin, heated electrically, and finally pressed at proper

electrically, and hashly pressed at proper temperatures into finished lumber. "These boards," states the Industrial Bul-lein of Arthur D. Little, Inc., "meet pre-determined specifications, with widths pre-viously anavailable, and with a uniform adherence to specification comparable to that of the steel construction industry."

The resin used in the process impregnates the board with vapors which are obnoxious to fungi and thus the long-sought fungusproof board is at hand .- Science Service.

"SCREW-SOCKET"

FLUORESCENT

THE accompanying photograph shows a new type of fluorescent lamp, which may be screwed into the conventional electrical socket without special installation or wiring, as completed by the Duro-Test Corporation. The new lamp will be marketed for commercial lighting as well as for certain types

The new fluorescent lamp, at top, and its hayonet-joint screw socket

of domestic illumination. It is estimated that all fluorescent lamps reduce current costs about 80 percent to give light equal that provided by the incandescent type of The tube itself, when it burns out. lamp can be detached from the starting device which forms the part which screws into the socket. In addition, Duro-Test's new fluorescent starting device uses only 212 waits

BIRDS OF PREY MAY CARRY RUBONIC PLAGUE

BI BONIC plague, like other forms of death in these days, has apparently taken to air travel. Not on the man-made wings of airplanes, but on the wings of hawks, owls, crows, and other predatory and scavenger birds, says the U. S. Public Health Service

The suggestion comes from William L. Jellison, assistant parasitologist at the Rocky Mountain Laboratory of the Service. Thirty years ago, Dr. W. C. Rucker made a similar suggestion, but limited it to one species of burrowing owl that shares habitations with ground squirrels and other rodents that car-ry fleas which are in turn the ultimate carners of the plague germs. Mr. Jellison, how-ever, greatly extends the list of suspected birds, to include two species of hawks, two of falcon, three of owl, and one species each

of eagle, magpic, and crow.

All these birds prey abundantly on the plague-carrying rodents. The scavengers, like crows, devour their catches on the spot, but predators, like hawks and owls, carry the carcasses to their nests, with the possibility of distributing the fleas either on the way or after they arrive, In several cases, these flesh-eating hirds were observed in attacks on rodents dead or dying of the plague.-Science Service.

SIMPLIFY YOUR TABLE-TOPPING

THE art of table top photography is con-tomally stressed by photographic writers s being one of the simplest of camera endeavors. Frequently, however, these same writers debberately contraded themselves by introducing methods and illustrations not casely within the reach of the average amatero Nevertheless, table-topping is a sim-ple exercise when discussed from the point of vow of the anatour worker. The truth is that there is table topping and table-topping in its most elaborate form it calls for trained, professional craftsmanship, as, for example, the miniature settings designed and executed lor use in motion picture studios

But, for you and me, table-topping means mething clse again It means, actually, a clear space on a table upon which are ar ranged a number of simple odds and ends either found around the house, purchased in the five and-ten-cent stores, or id you are at all handy, made by yourself

Your principal difficulty will be in providing suitable figures. If you can make them yourself, so much the better, but most of us cannot However, the little non and other toy figures in the stores will regally do the trick admirably

Another feature of table top set-ups is the question of furniture Occasionally it is pos sible to pick up miniature reproductions of fornitite pieces but the best procedure is to make the formula yourself. This is not as deficult as it may sound Ordinary card board will often serve the purpose and a column may easily be simulated with a small cardboard mailing tube or even a sleet of paper twisted round and held together with a strip of adhesive. An excellent medium for miniature furniture-making is balsa wood, now obtamable in home custsman packages, comprising an assortment of

4bove: Making the set-up for "The Shadow of the Law," as described in the text and, below, the result

balsa wood in several thicknesses and

lengths.
"The Shadow of the Law" illustrates what can be done with a couple of tron figures to bought in the five-modern-ent store. These consisted of a policeman and a strolling pedestrian. The objective was to a trange in a simple manner a street scene showing a many opticeman, whose body cast a long shadow down the sidewalk, while a civilian approached him from the opposite direction.

Set-up for "Performance"

A piece of cardboard was wored with a perhanfe at one inch nitervals over a space about four inches wide, and a strip of black. Stocks hape separated this portion from the rest of the cardboard. Thus, when the light hearn was directed at the low angle noseary for the progression of the long-should research the properties of the provided the effect of separating grooves between the "stone slabs" of the sidewalk.

In order to complete the impression disired, no effort was made to continue any further in the matter of a set up other than to provide a black void beyond the sidewalk ofge. This was done by placing the cardboard on a black cloth and so arranging the light that very little of it reached this cloth. The spotlight used to illuminate the subject.

Huminated by the large candle to down left of figure. No other illumination was employed for this

"Darfamana"

was, therefore, cut down in heam size through the se of a price of cardibard in the center of which a hole was cut of a p proximately the damater required to bring about the desired limitation of the illimnated area in order to throw some light into the face of the poleceman a reflecting screen covered with silver foll was placed as shown. This caught some of the light, and, by satisfied angling of the screen, brought a little light onto the from of the brought a little light onto the from of the law been disk. With all the consequence of the consequence of the consequence considerably, the exposure was about 20 seconds.

Given an interesting figure, several variations are possible with different lighting arrangements. This is illustrated in the figure of the costumed dancer, which is another 10 cent purchase

Simulation of a stage performance by the dancing figure was accomplished by cinploying twelve tiny birthday caudles set up on two wooden blocks before a "stage" consisting of a hox covered with black cloth. For the background a sheet of hight-toned cardboard was used. The twelve candles were lighted quickly one after the other just before the exposure was made because these tiny candles burn away rather quickly To avoid including the lights in the field of view, as well as to prevent unwanted light reaching the lens and causing possible glare, the lighted candles were shielded from the lens with a cardboard blind. The presence of so many light sources caused a multiplicity of shadows to appear in the background but hecause one shadow was partially merged with the succeeding one and because of the large number of light sources, no one shadow was definitely apparent. If it is desired to show such a projected shadow, the best method is to use only one candle, a large one, placed to one side of the figure and at about the level of the small candles or even a bit higher, provided the flame is not included in the comers view

AGFA CAMERAS

public lecture in New York City in which he described his experiences in shooting color pictures with his Leica camera, declared that he learned the proper exposure time to give under various lighting circumstances by making a series of experimental shots over a period of time. From the rescribes as his basic exposure, namely, 1/6.3 at 1/60 of a second. Where a higher shutter speed is required he simply runs down the scale and opens the lens wider in proportion to the speed required to stop the action involved, using the stop f/15 and a shutter speed of 1/500 or 1/1000 of a second when necessary. Similarly, in the case of subjects that are a bit too dark for the basic exposure set up he opens his lens wider for the basic shutter speed

There is much to be said in favor of Mr. Dmitri's method and it would repay every worker to set up some similar basic ex-posure method whether he shoots in color or black and white, Mr. Dmitri says that he hardly ever uses an exposure meter because his exposures have become standardized by his personal method of working. However, it must be remembered that Mr. Dmitri shoots entirely in color, using 35mm Kodachrome exclusively. Having used this over a long period of time, he has become thoroughly familiar with the results he can expect under various circumstances For gen eral photography an exposure meter would seem to be one of the musts in the photographer's equipment; however, the worker must train himself not to rely absolutely on this guide to correct exposure, but to think for himself as well, and to interpret the readings rather than to follow them without question

One of the surest wars of acquiring the ability to make such interpretations is to about a number of different exposures of the same subject under the same lighting conditions and then compare the results. Pick out the negative that seems to you to or more than the actual meter reading, and just your meter calculations accordingly For example, if the meter said f/8 at 1/100 and your shot at J/11 seemed to give the better negative, all you will have to do therester will be to take one stop amulier than the moter decases, adjust the shutter to Weston rating for your film.

COLOR DEPARTMENT

RECOGNIZING the wide interest in color in supplies and information as unterested and to bring greater demands for supplies and information as unte sees on, Willoughly's camera store in New York City lass inaugurated a special department in its store manual by no color expert ready also and equipment. The management express and expuspment. The management express that thus department will fill a real need and become out of the sure's most active services.

FLOWERS IN THE PARKS

NE of the chief reasons for the failures experienced by amateurs in shooting pictures of blossoms and flowers is due to the fact that too much of the subject is included in the view. Of course, we know it is very difficult to isolate a subject in such a manner that it is made to stand away from

the rest of the branch and still be appropriately lighted and have the sky for background. There is always some way out of the difficulty, even if it becomes necessary for someone to hold a branch in a certain position for the duration of the exposure or to hold obstructing branches out of the way

"Japanese Magnolias"

of a particular subject. Lighting as very importunt, for a promising subject will be missed completely if the lighting is unstituable. One of the most effective methods is that of back lighting, illustrated in the accompanying picture of magnolas. Notice, too, that an effort was made to bring about a good balance in the composition by including the bud in the lower left-hand corner.

X-33 FINE-GRAIN

FORMULA

UNTIL recently a closely guarded laboratory secret, the formula from which the developer X-33 is made up has now been disclosed by the makers. The formula follows:

The chemicals are mixed in the order given, each thoroughly dissolved before adding the next. The solution may be used inmediately after cooling.

RAYGRAM CORP

the front of the subject is 20 inches from the lens and the back of the subject 30 inches from the lens, namely, a depth of 10 inches in all. In order to determine the point at which the camera lens must be focused, it is necessary first to multiply the two distances, namely, 20 by 30 and the result by 2, which comes to 1200, Next, add the two numbers, 20 plus 30 equals 50, and divide this into the first result, 1200. The answer is 24. Therefore, it is necessary to focus on a point 24 inches from the lens disphragm or 6 inches from the back of the object. Focusing on this point is done with

the lens wide open and the closing down of

the lens brings both front and back of ob-

ject into sbarp focus TIME EXPOSURES AT

THE ZOO

MANY persons are discouraged from pic-ture-making in 200 interiors because of the poor lighting available. However, if one watches his chances he will frequently be rewarded with opportunities such as that encountered by this department in the alligstor subject here illustrated. The alligators were as still as though carved in stone and a full, unobstructed view was afforded by the large window behind which they were en-

"Alligator Siesta"

joying their afternoon siesta. Because there was such a large shedow area, a relatively long exposure was required, especially in view of the stop f/8 that was required to bring the several subjects into sharp focus. An exposure of 20 seconds was made possible without the use of a tripod by resting the miniature reflex on a ledge and slightly tilting the camera by tucking the front of the eveready case under the camera.

KALART CONTEST

TWENTY-FIVE awards of \$10 each are offered in a photographic contest sponsored by the Kalart Company, who will pay the total of \$250 for the best pictures taken with a Kalart Micromatic Speed Flash. Closing date is December 1, 1939, and there are no restrictions as to type of flash pictures time when taken, and so on. Print sizes should range from 2% by 3% inches to not larger than 11 by 14 inches. Enlargements and contact prints are both acceptable, Nega**_and** you're photographing in color

N SPITE of its modest price, this Kodak Bantam f.5.6 gives you Kodachrome (full-color) transparencies that you'll marvel at . . . because they're so beautiful and lifelike, and because they're as easy to make as regular snapshots.

And just wait until you project your Kodachrome transparencies on the screen-that is something!

All three Bantams listed below have fast lenses, fine shutters, upto-date features-and all can be counted on for excellent results in Kodachrome full color as well as in black-and-white. Kodak Bantam Special, pride of the "Bantam Family," is one of the handsomest and most capable of all miniatures.

Kodak Bantams are just palm size. But when you use them for regular black-and-white pictures, modern photofinishing methods give you big prints (23/"x4"). For black-and-white pictures only, the "Family" also includes an f.6.3 model at \$8.50 and an f.8 model at \$3.95. At your dealer's . . . East-man Kodak Co., Rochester, N. Y.

SHADOW ON PATTERN

N intriguing pattern such as that of the floor in the illustration would normally be lacking in picture interest, but add to if the lively shadow of the walking boy silhonetted against the bright sky and you have

"Patterns"

a subject worth shooting. The stop fold was used in order to get satisfactory sharpness from foreground to boy subject; the time being late afternoon, 1 25 of a second was the fastest shutter speed we could attempt This was not sufficient completely to stop the movement of the boy's raised leg, but this does not appear to have seriously ham pered the general effect.

OVAL TABLE ELECTIONS

TWO recent additions to the Oval Table Society, Inc., of New York City, sponsor of several of the most important photographic shows in recent years, have been the electhe country's leading color photographer, and C W. Gibbs, A.R P S, a man of the laboratorics who has become widely known as a writer on photographic subjects. The Society's ruster of some of the best known photographic workers in this country is thus increased by two names with enviable repu-

ARGUS RADIO PROGRAM

A SERIES of transcribed radio programs featuring Karl A. Barleben, F.R.P.S., is being sponsored by the Isternational Re-search Corporation under me title, "Today's search Corporation under the line, about a Candid Story" The series is being used by photographic dealers' in several cities throughout the country over their local radio stations. The series is one of the first camera programs to be sponsored by a photographic manufacturer and presents the fast-action, true-life type of camera drama.

"STROLLING SHADOWS"

OPPOSING shadows in a diagonal frame constitute the chief attraction of this picture shot from the seventh floor of our apartment house, and the little dog helps to fill in an otherwise barren space. The height being so great, we were obliged, by the focal

"Strolling Shadows"

length of our lens, to choose patterns that would compose satisfactorily in a large space. To this end, we watched the "strolling shadows" as they passed in and out of the area until the idea of opposing figures brought the answer to the problem and provided a picture in which the figures, though small, adequately filled in the space by the length of their shadows.

SPOTS ON SEPIA PRINTS

To remove the stains and spots which occasionally appear on sepia prints, practical workers have found hydrogen peroxide to be fully effective. This is simply poured over the spots or stains or applied with a wad of cotton. A rinsing completes the job

CAMERAS AS POLICE EQUIPMENT

THE Beverly Hills (California) Police Department is now equipped to go after law violators both with gin and camera Re-cently Police Chief Charles C. Blair, of that department, bought a number of Univex Mercury cameras for use by all officers of his department. Which prompts F. G. Klock, of the Universal Camera Corporation, to remark that he wonders "if the day isn't rapidly approaching when every city policeman and town constable will tramp his beat with a candid camera sling over his shoulder.

What a whale of a difference a GREEN LIFA FILTER Makes . . . use the correct filter with the right emulsion!

Present-day panchromatic emulsions are slightly over-sensitive for the red end of the spectrum. And, since panchromatic emulsions are popular, it is important that you use the right type of filter when taking scenes in which red, yellow and blue predominate.

You can, of course, use a yellow filter. However, in order to obtain full correction, a Green Lifa Filter "must". This green filter not only holds back the blue light, but also corrects fully for the yellow and red.

Let us give you a visual explanation. Here are two photographs of a still life . . . showing a blue bowl, red apples and yellow bananas. The first picture, taken with a yellow filter, is sharp, but the red tone is only half-heartedly rendered . . .

The second picture, taken with a Green Lifa Filter, shows a sharp delineation between the yellow and the red. Correct monochrome valuation is achieved with satisfactory contrast. You, too, can get perfect results, working indoors or outdoors, with Green Lifa Filters. Try them!

HENRY HERBERT

of any movie reel and holds film securely in place. Clip provided with matte outer surface, upon which film title, number or other distinguishing mark may be written in ink, crayon, or pencil.

19 POINT WILLOLTTE ENLARGER (\$39.50 without lens): Enlarges all size negatives from 35mm to 2½ by 3½ inches, uses stand-

ard 75-watt opal bulb; employs two 45-inch condensers which can be removed for cleaning by loo-ening two screws; lamp house and throat of enlarger well ventilated, on-hand raising and lowering mechanism, with automatic brake to prevent slipping when de-

sired height is reached, and screw knob for locking, swings in horizontal and vertical planes for correction or caricalure, auto matically returns to true vertical position by locking knob, distance from center of lens to column can be changed from 91/4 to 121/2 inches, enlarger housing is separate unit which can be removed for storing away when not in use, design of enlarger throat gives 1/2 meli space to insert negative carriers from front, automatic centering of negative carners; choice of metal negative carriers with guide puis for films in rolls, accommodates larger films, permitting enlargement of portion of larger negative; long extension leather bellows, rack and pinion focusing; detachable lens board for lenses of different focal length; swinging red filter, baseboard, combined with paper drawer measuring 1414 by 151/4 inches, measures 17 by 21 inches, flish type toggle switch in side of cabinet, 30 inch steel chromium-plated column permits enlarging on base to 12 diameters with 2-inch lens, larger by projection over edge of cabinet or by tilting enlarger

But Bit. Monorous Virwing Filter (\$1) Designed to give our-color rendition of scene to be photographed on pauchtomatic film Filter made of dyed-in the-mass glass, has no gelatin or plastic composition. About two inclus in diameter.

SYNCHHOSCOPE. Device for testing synchronization of camera shutter with peak intensity of Photoflash bulbs. Electrically op-

crated from battery of any Kalart Speed Flash and does not require use of flash bulbs, film, or darkroom. Clear visual indication given of shutter timing efficiency. Device is fastened in front of lens and shutter

or in front of lens and strater by sliding adjustable from the first possible in height to center with lens, as they quickly into front window while releasing synchronizer, two shis are seen as they quickly flash by in opposite directions. Synchronizer is properly adjusted if the two slits are seen onle to red as one line. Electric lamp or daylight through open back of camers will show up the shis

WILLO NEGATIVE CARRIERS (\$1, 35mm; \$2, 2½ by 2½ inches): Smooth, scratchproof "book" type negative holder device

HARD TO GET? NOT WITH A CINE TELEPHOTO LINE

The toughest shots become easy with a Wollensak Cine Telephoto Lens. No a Wolfensak Cine Leiephoto Lens. No wonder—the timid deer never knew a picture was taken—the camera was 200 yards away. Take "close-ups" from a distance for humor, variety, thrills... use a Wollensak Cine Telephoto Lens.

CENTRAL

made of durable, rustless Alleghany stain-less steel, and available in two sizes to fit all standard miniature enlargers: 24 by 36mm (1 by 1½ inches) and 6 by 6cm (21/4 by 21/4 inches) Accurate design assures perfect masking to the practical dimensions of the negative. Removal and insertion of negatives made convenient by provision of a "lin" at the two free corners of the carrier.

ROCKER RINSER (\$2): Device for washing prints and flat negatives in 15 minutes. Comprises 11 by 14 inch tray with open channels at four cor-

ners, divided by barrier into two sections, one of which is large enough to take prints or negatives up to 8 by 10 inches, and other taking sizes 4 by 5 inches and smaller. Under side of device

fitted with off-center beam, on which unit rocks. In use, device is placed under faucet in flat sink or tub; stream strikes deflecting baffle on barrier between two print compartments. As one section fills with water, it tilts and second section starts filling. Water meanwhile runs out of first section through two vents at corners, aguating and flushing prints or negatives at same time. Rubber bumpers prevent noise.

SOLAR SPECIAL 4 by 5 Enlarger (\$49.50). Designed to take negatives up to 4 by 5 inches Dif-

fused light source is principal feature. Lamp house counterbalanced to permit one hand operation in raising and lowering Enlarger furnished complete with roomy base-board.

LEITZ FILM TANK: For loading bulk 35mm film in full daylight into camera magaines. Accommodates bulk load of 300 feet of 35mm film. Loading done simply by turn-ing conveniently located crank. Film safeguarded against scratching or fogging. Constructed to take Leica camera magazines, but also useful in loading Contax magazines.

CURTIS COLOR SCOUT (with Goerz Dogman f/4.5, 71/2 inch lens, three registered holders, lens shade, carrying case, and three dozen loads of

sensitive material. \$325; same outfit with Bausch and Lomb IIb Tessar //6.3 in Compur shutter, \$280): New, two-mirror, three-color camera, that provides 21/4

by 31/4 negatives. Weighs 5 pounds; with lens and one dozen loads of film, total weight 7 pounds. Size of camera comparable with 2¼ by 3¼ reflex camera. Constructed entirely of aluminum alloys, embodies features making for precision of register, color balance, freedom from internal reflections and flare, maintenance of even illumination of the three emulsion apertures, convenience

SAVE your flat Negatives

Print on No. 5 paper from negative Spariting print on No. 5 paper from of flat dell subset full decisions.

Quickest, essiest way to make flat neg wattenest, easiest way to make flat nega-tives yield sparking prints, so save under-developed usgatives, to improve beilliance of fine grain ministure negatives. No fuse, No bother. Dissolve contants of VICTOR tube or bottle as directed on label. Immerse nega-tive in solution a few seconds, wash and dry.

Tubes, 25c and 45c . 16 oz. Bottle, 85c

James H. Smith & Sons Corp. 97 Celtax St.

lcally placed in series across line, each lamp receiving part of total line voltage. At this reduced voltage, lamp life increased to several hundred hours instead of usual two to sex hours. Reduced illumination is ample for focusing. "High" value needed only for determining best placement of lights and when actually shooting pictures Entire unit enclosed in steel box four inches square, two inches high. All current carrying parts rated to handle 1200 watts.

CROSLEY CAMERA PRESS JR. MODEL (Complete with reflector and steadying handle, \$7.95). New camera design and construction. Back of camera curved to bring 35mm film to good plane of focus, High-lights: universal focus, no adjustments required, with usable depth of field three feet to infinity. Built-in flash bulb synchronizer and battery supply When button is pressed to make exposure, flash bulb is automatically flashed. Automatic film transport. Automatic locking device prevents over-winding, Camera loaded in 10 to 20 seconds. Automatic counting mechanism. Makes eight 35mm exposures to the roll. Available in black and aliminum finish. Measures 4 inches long, 3 ½ inches wide and 2 ½ inches deep

THATHAMMER THREE 11-10 (\$10, Head or tripod alone, \$5.50 each): Titpod and pan head combination. Tilt-pan head has natural satin finish, incorporating Thal-hammer "Instant-On" Plug. Tripod made of selected, seasoned wood, finished in clear lacquered metal parts, polished, or coated with black enamel Head or tripod may be purchased separately

MINI ELECTRIC EXPOSURE METER (\$12.50. with neck cord and a copy of "exposure meter manual' with film speed insert): Measures 174 by 214 by 1/4 inches, weighs

ing parts fully en-closed. Small hinged flap protects sensitive cell when meter not in use. Mint is pre-set for any given film and shutter speed (or cine frames per second), no further

31/2 onnces. All mov-

adjustment being necessary until change is desired in one of these factors. Meter indicates proper stop to employ. Cell is placed at acute angle, thus excluding top light in-fluence Protecting flap folds down when meter is in use, climinating reflections from foreground, when using meter on snow, water scene or similar subject Black finish with silver figures. Necessary figures large and clear

JACK POWEL ETCHING SCREEN (11 by 14, \$3.50; 8 by 10, \$2.50; 5 by 7, \$1.50): Designed to add texture to photographic prints. Styles include Renaissance for trans forming ordinary portrait or landscape into "Old Master"; Jack Frost matrix for crystal pattern; tapestry for distinctive textured quality; bromoil for imitating bromoil process; paper negative to cause picture to assume air brushed or charcoal appearance; Steeline to impart effect of fine steel en-ORIFFITH, INDIANA graving, and Freeline etching screen that gives the snap of a hand-etched print.

HERE'S the book that has everything in photography — at great money-ear-ing prices. Complete line of modern candid, still and home movie camera. .. supplies and equipment. ENLARGEMENTS XXX

JACOB DESCHIN, conductor of our "Camera Angles' department, will nsuer in these columns questions of general interest to amateur photographers IJ an answer is desired by mail, enclose a stamped, addressed envelope. Queries should be specific, but Mr. Deschin cannot undertake to draw comparisons between manufactured products nor to advise on the purchase of equipment or materials - The Editor

Q. I am in the market for a 35mm. ra and would like your unbiased opinion on the following: I have nurrowed the field down to include three earnerus, two with Compur shutters to 1/500 of a second and the third with focal plane shutter speeds to 1/1250. The first two are equipped, respectively, with an f/2 and an f/2.9 lens, and the last with f/2.8 lens. All have coupled range finders. I would like to take pietures under adverse conditions, including indoor and night shots, I would appreciate your comparison of the three cameras, including the following: Shots possible with 1/2.9 lens and its limitaons, quality of lenses, advantages or disadvantages of the two kinds of shutters, whether 1/1250 of a second ca be used with an //2.8 opening. I would also appreciate the names of better quality cameras in the same price class and also the names of enlargers,-S. J. S.

SCIENTIFIC AMERICAN

A. It would need a Solomon greater than he of the Bible to tell a man what camera he should buy, so many are the variables and so much depending on the individual's requirements and his personal taste. It seems to us that probably the best adviser on this score is the local photographic dealer, Usually he has no axe to grind, he sells all kinds of cameras and he would just as soon sell you the one as the other Let him give you the benefit of his experience, based on his contact with the many persons to whom he has sold cameras in the past The three cameras you mention all have their good points and all will make good pictures once you learn how to use them.

Pictures under adverse lighting conditions may be taken with any lens provided you allow enough exposure Even moderate snapshots can be made in poor light if this light is sufficiently close to the subject and your film is of the "super" type. Under certain "adverse" lighting conditions, even a lens
of f/1.5 speed will be inadequate.

On the question of lens choice, see our reply to J.G.B., June issue; the 1/2 you refer to may possibly have a little "edge" on the others. If very high shutter speeds are what you want, you will find the focal plane shutter preferable on this account.

Many prefer the Comput because it has a tradition of reliability Nevertheless, some of the highest priced and most efficient instruments on the market today have focal plane shutters and are none the worse for bring so equipped. The use of very high shutter speeds is entirely a matter of the amount of light available for photography and the sensitivity of the film emulsion in your camera. Therefore, a 1/1250 exposure at f, 28 or even smaller stop is entirely pos sible; generally, the necessary light volume will be available only when shooting outdoors on a bright day.

As to your last request, you may find the an-wer by making a tour of the photographic shops or by writing to the manufacturers and dealers whose advertisements appear in these columns

Q. 1 .-- I have read statements of certain professionals who mentioned that they had bought a Contax and had it thoroughly checked by Carl Zelss before they went to work with it. Does this mean that some lenses of the Sonnar //2, 5cm specifications, for instance, are capable of hetter results because of the greater accuracy in manufacture? If so, will Carl Zeiss cheek any purchaser's camera, so that he may feel confident that, from the equipment standpoint, Toni Frissell has no better chance of getting a sharper negative than him-self? 2.—Is there any possible way of obtaining a sharper projected image for enlarging than using my Sonnar //2, 5cm lens in the Magniphot enlarger? Is there meant to be any adjustment on the light source in this enlarger, or is it fixed? Have you ever seen a direct enlargement made from any 35mm neg tive to the tremendous size of Toni Frissell's exhibit prints? Even considerrissell's exhibit prints: even constitution in intermediate negatives, how is it possible to preserve such hair-line detail? And where did the grain go? 4.—

Who makes the enlargements for the Zeiss and Leica exhibits?—H. W. E.

A. 1.—Carl Zeiss or any other company will gladly check the accuracy of a camera lens for the mere asking. The reason a pur-chaser desires a check-up is due to the natural feeling that a camera handled on a store

counter, perhaps dozens of times before the actual purchaser came along, may have been slightly mishandled by inexperienced hands. A professional photographer must be sure of results from the stert, particularly if he s about to undertake an important assign ment. Even if he wishes merely to try it out for a while before actually getting to work with it, he wents to be certain that he is starting off on the right foot and that if there is something wrong with the results, it is probably due to his unfamiliarity with the workings of his camera. Provided you operate the camere properly, your negatives will be just as sharp as those made by Toni Frissell or any other experienced professional worker The lens that you get with our camera is not a whit better or worse than a similar one furnished to Toni Frissell.

2 -The sharpness of the projected image is governed by the precision with which you focus the image on the easel and your Sonnar will give you this sharp image if you focus carefully and accurately. The light source is admistable as to distance from the negative holder

3 -We have seen prints of this size and even much greater made from a single 35mm negative. The preservation of detail and the lack of visible grain ere due entirely to good processing throughout from the development of the negative to the final print-We have it on the word of the Zeiss in# people that the Frissell enlargements were made directly from the 35mm negative and that intermediate negatives were not used. In fact, they add, direct enlargement is one of the chief contributing factors to that preservation of detail and tone gradetion which you admired.

4-The enlargements for both the Leuz and the Zeiss exhibitions are made by the individual photographers themselves possible exception is in the case of displicate prints for traveling exhibitions or when the company has acquired a negative as the result of a competition or otherwise. The large mursls are naturally made by an outside finisher because the average photographic worker does not have the facilities for turning out prints of this size.

Q. I have a Rolleleord f/3.5 and would appreciate advice as to what lens opening and distance to set for fixed focus exposures.—W. L. P.

A. If you will set the distance at 10 meters and close down the lens displiregm to f/11, everything will be in focus from five meters -that is a little over 16 feet-to infinity. The stop f/16 will give you a still deeper field of focus, namely, a little under 12 feet as the closest distance when the meter scale is set at about seven meters.

Q. I recently constructed a small print dryer similar to commercial dryers, topped with a curved chromium plate and covered with a removable piece of canvas. Heat is supplied by two 100-watt electric lights in the interior. The dryer works well when ferrotyping glossy prints, but causes matte prints to wrinkle all around the edges. Is there any way that this wrinkling can be remedied? The first batch of prints, by the way, usually does not wrinkle, but the following batches do.-W. H. B.

A. Application of too much heat is prob-

edges of the matte prints. Since the first batch of prints does not wrinkle, it is suggested that you attempt to determine the approximate temperature at which the first batch was dried and try to maintain this heat, as nearly es possible, for the succeeding batches,

Q. Is there any difference in performance, other factors being equal, between dilters of the stained opticalglass type and the gelatin-cemented-inglass type? Cemented gelatin light filters are frequently described as being available in A glass or in B glass. Just what is the difference between A glass and B glass? What, in a practical sense, ie the importance of this difference in general photography?-J. A. R.

A. So far as performance as concerned, there is practically no difference between the stained optical-glass type and gelatinbetween-glass types of filters. The principal difference lies in the fect that masmuch as in the one case we have a solid, colored disk of glass, and in the other we have a piece of soft gelatin between two protecting cover glasses, the latter is obviously sus ceptible to certain hazards from which the other is free. Among these hazards one must include the facts that the latter may not be exposed to the sun for too long a period, must not suffer too great pressure, and must generally be given greater care than the solid glass type. The A glass consists of so-called "optical flats," of the highest quality but too costly for general photographic use. The B glass filters are the most generally used and are satisfactory for regular photographic nurnoses.

Q. Will you please give me what in-formation you have on the subject of enlarger adapters for conventional cameras? I am informed that such an adapter, when properly adjusted upon th ordinary camera, with back removed, yields quite satisfactory enlargements. The camera lens, of course, serves to expand the image and, for this reas the cost of the device is relatively low in comparison to the prevailing prices of regular enlargers.—G. W., Jr.

A. There are available such enlarging attachments, permitting the owner of a camera equipped with a removable back, to convert his camera into an enlarging outfit by altaching the enlarger liousing unit and negative holder. The projection of the image is usually horizontal instead of the popular vertical arrangement employed with regular enlargers. The cost of such a unit is con siderably lower than that of a regular enlarging outfit, but it is significant that these nnus are not especially popular, workers generally preferring the complete outfit rather than an adapter.

Q. I would like to learn how to develop my own pictures. Could you give me a list of what I would need and directions?-J. N.

A. A number of developing kits are available containing the necessary equipment and supplies for developing negatives and making prints from them. These kits also include a short explanation of the photographic process and directions for developing and printing. In addition, it is suggested that you obtain a copy of an inexpensive elementary handbook, which your dealer can supply for 25 or 50 cents.

NIKOR **Anti-Fog Stainless Steel** TANKS

NEW ADJUSTABLE MODEL

for Cut Film and Film Packs from 21/4 x 31/4" to 4 x 5"

THE Book Department of Sci-entific American is conducted, with the co-operation of the Editors, to make available for you a comprehensive book service. Each month the Editors select and review in these columns new books in a wide range of scientific and technical fields. In addition, they are ready at all times to advise you regarding the best available

books on any subject. You are invited to use this service freely. Tell our Book Department what

kind of books you want and you will be furnished with a list of available titles, including prices. When inquiring about books, please be specific; remember that we can be of the greatest help only when you tell us just what you are looking for.

MEN. MIRRORS AND STARS

By G Ldward Pendray

NEW edition of a book which many A amateur telescope makers purchased four years ago when it first appeared, because of its large content of elementary background about telescopes and of lore of professional telescope makers of the past. Chief addition now is a chapter on the 200mch telescope. (341 pages, 5½ b) 8 inches, 78 illustrations)-\$3 10 postpaid-A. 6 1

WHAT SNAKE IS THAT?

By Roger Conant and William Bridges

COMPILATION of careful descrip-A tions of the snakes of the United States, illustrated with numerous beautifully made line drawings to show types of scales, head structure, and body markings of the snakes discussed This would be, in our opinion, a perfect reference book to carry away on vacations. Complete index, a treatment for snake bites, and a brief snake dictionary are included (163 pages, $5\frac{1}{2}$ by 8 inches)— \$2 10 postpaid -F, D M.

YOU'RE THE DOCTOR

By Victor Heiser, M.D.

DR Heiser, author of "An American Doctor's Odyssey," now gives us a charty, reminiscent, anecdotal book on foods and how they affect us, likewise on ways of living, together with the whys Absorbing reading and full of common-sense health information (300 pages, 51/2 by 8 mehrs) -\$2.60 postpaid - 4 G L

LIFELIKE PORTRAITURE WITH YOUR CAMERA

By W. H. Doering Translated and adapted by L. A. Leigh, F.R.P.S

COMPREHENSIVE work on what is A probably the most important subject type in all photography, this book takes the reader on a practical tour of all the important aspects of postrasture. It tells him what differentiates the snapshot portrait from the more exalted types. It classifies cameras and xplains their special usefulness in this field. A valuable section is that devoted to lenses, There is also helpful guidance on the subjects of selecting the proper negative material, development, retouching, paper, com-

position and trimming, and the mounting of the funshed picture. A helpful index, many fine illustrations, and lighting diagrams plus good readable type make this book will worth any amateur's money (108 pages, 58 photographs and many diagrams, 6 by 812 inches 1-\$2 10 postpaid - 1 D

POISONOUS PLANTS OF THE UNITED STATES

By Walter Courad Muenyche

PIANTS causing poisoning when caten or by contact or by mechanical injury to man and animals are treated by name, descreption, distribution, and habitat, also ac cording to their personous principle, conditions of poisoning, symptoms, and sometimes by remody, in this reference book. It includes monerous full-page drawings of the plants and their parts (266 pages, 5½ by 8½ inches, 75 illustrations) -\$160 postpaid --A. G. I

ARC WELDING IN DISIGN, MANUFACTURE AND CONSERVATION

I dated by The James F. Lincoln Are Weldeng Foundation

REPRESENTING a compilation of pation sponsored by The James F I medin Are Welding Foundation, this volume is amazing in several ways his wealth of material may be noted by its total of 1408 pages. The papers reprinted or condensed therein discass the practical aspects of welding, the great savings effected by its use, and ingenious solutions to construction problems that have been actually encountered by the entrants in the competition Hundreds of thawings, photographs, tables of costs and specifications, and mathematic calculations are included This could become a bible for all those interested in welding (1408 pages, 6 by 9 mehes, hmp leatherette) -\$1 50 m United States, \$2.00 clsewhere,-F. D. M.

YOU AND YOUR MONEY

By C. Donald Dallas

NOMMUNISTS will not wish to read this Colume by the President of the Revere Copper and Brass Company The author discusses logically and, we think, more objecrively than would his opponents, the question of capitalism and industry obtaining in this country today. Naturally, communism comes

in for some straightforward criticism. Long folding graphs are included to show 100 years of conomic progress and 150 years of real-estate activity. From these the author draws important conclusions regarding our democracy (85 pages, 5½ by 8½ inches.) - \$1 60 postpaid -F. D. M.

MAHAN

By Captain W. D. Puleston, U. S. N.

THE writings of no American military man bave influenced the world's military tactics so greatly as have those of Captain Mited Thayer Mahan, United States Navy The naval academies of the world still study his books on naval strategy, and it was these that strongly influenced the naval building activities of world powers before the World War His writings were indeed carefully scanned by all naval students whether they appeared in book or magazine article form. (Several of his articles appeared in Scientific American)

The present biography—by a former Director of Naval Intelligence, and, meidentally, a contributing editor to Scientific American - is a sympathetic and compelling story of the life and work of this man who is too lettle known to the layman. It might be aptly characterized by a chapter heading near the conclusion, entitled "Mahan's In-fluence on History"—(380 pages, 6½ by 912 inches, 16 illustrations, bibliography, initex 1-\$410-F, D.M.

PRISS PHOTOGRAPHY WITH THE MINIATURE CAMERA

By Duanc Featherstonhaugh

WORKING press photographer with A many years of experience in the field and no prejudices to handicap him, tells the amateur how he may turn his spare time into spare dollars by making pictures for the press. The book is completely prairical and takes in as much of the field as will he useful to a beginner. The book is well illustrated but lacks an index. (159 pages, 5½ by 8 inches, 25 photographs.)—\$2 10 postpaid—J. D.

IT'S NICE TO KNOW PROPLE LIKE YOU

By Harry Walker Hopner

ANOTHER of the recent spate of success-ful books on getting along with other people, and most interesting reading it is Objectively described, however, most of the recommended methods amount to being twofared, using subtle flattery, saying insincere things, and being all things to all people as the occasion seems to call for, but there is

TELESCOPTICS

A Monthly Department for the Amateur Telescope Maker Conducted by ALBERT G. INGALLS

PEW refracting telescopes are made by amateurs—perhaps because of the time and accessories needed, but largely, it is suspected, because in earlier years when amateurs regarded optical work with awe and mystery a tradition that objective lensmaking was very advanced work became established and has not yet been seetched Yet, whenever somecuse who has made one

Figure 1: Garrison and refractor

writes to this magazine, he never mentions any especial history of trials, 'Industrons, and headaches. The job, with its four surfaces to work, is a bit tedious, and probably should not form the beginner's madern optical work, but for all its tedium it is not more difficult than reflector making not more difficult than reflector making the working tolerance, in fact, is not so close. It is suspected also that in earlier years many who dured not tackle a refractor convinced themselves, because of this fear, that the reflector was upperfor But most persons who are honest with themselves and who know both instruments do

not say this. Each type has its superiorities, one superiority for the refractor being much steadier images.

In Figure 1 is an 8" refractor made by H. P. Garrison, R.F.D. 1, Oceanside, Calif, working from the very detailed instructions by Haviland in "ATMA", the companion volume to "Amateur Telescope Making"

"The objective lens," Garrisou writes, "was made from a part of Chance Brushers liard crown and deuse flint, ground to a focal length of 134%," or /1/10 51 1 pent much time regranding and polshing five times, but 1 did not mund that because twa-learning all the time Now I have a lens that will stand 75 dameters' magnification to the aputitor inch when the seeing is good, and I feel! an were well repaid for the extra

"The mounting is made from Chevrolet truck peris, steel pipe, and boiler plate, and the axes are mounted on ball bearings. The tube is of 20-gage galvanized iron 8½" in diameter.

"The mounting works very smoothly bill, in the wind, as shown in the illustration, taken before a 14' by 14' roofless observatory with 6' walls was creeted, it was very

"The cell, Figure 2, is made of aluminum cast in one piece, and is held in place by means of brass clips. This permits removal of the leas without disturbing the adjustment."

PRAMED attractively in the twigs of a Pneghboring tree, as shown in Figure 3, stands the huge, 137 dome for the 200° telescope, atop Mt Palomar, California, with the great mounting inside practically ready to receive the big mirror next year This artistic photograph was taken by Ted Watterson, official photographer at Mt Palomar

Figure 4 is a 1/340-scale replica of the same great dome, cast in brass and aluminum by Fred Ferson, 404 Reynoir 5t, Bilox, Miss, author of the chapter on molding and casting in "ATMA". The patter and presented to Ferson, a friend. Ferson them, and provide the authority, method them, and makes of this replica is most attractive desk, and of this replica is most attractive desk, and of the replica is most attractive desk, or other, comment—suitable last for adaptation as a cigaret humdor, ash receiver, or other ultiny Ferson hopes to malal in some of these replicas a model of the 200° telescope table, if there is enough demand.

The base is 8½" in diameter, is made of brass, weight about six pounds and is let 'tered' Two-hundred Incli Telescope Observatory A D. 1940. "This brass base includes an integral standing collar part reaching upward as far as the bead seen above the entrance dourway. The upper portion is east

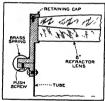

Figure 2. The clip-attached cell

in alimmum, contrasting attractively in hie with the brass base, and consists of a hollow spherical dome 5%" in diameter, to which an accurate replica of the shutters is attached facely. This upper portion may be rotated, as on the original, also lifted off to get at the interior, which is machine-finished.

Figure 3. Big dome at Mt. Palomar

Figure 4: Ferson's big-dome replica

Sharp-eyed comparisons will reveal that the entrance door in Figure 2 differs from that in Figure 1, the original. These, however, are different doors and on different sides, the door in the replica being the huge one for the introduction of the big mirror and the other merely for the introduction of the autonoments.

In Figure 5 are two lesser items cast by casting-enthusiast Ferson. The larger is a

Figure 5: "Mirror Maker" and "Nut"

THE BEGINNER'S CORNER

PORTABILITY around a yard hat no farther is often desired in a telescope and the two shown here were designed for that purpose; they are mounted permanent by on wheels. The one at the left is a 6" reflecting instrument built by Robert M. Peterson, 455 Seminole St., Oradell, N J., apparently with cart or perambulator wheels as its base. The mounting is the regular double yoke type, which is very easy to build and very solid. The tube shown is octagonal, made of wood, an excellent substance for a telescope tube-better, many think, than metal because a slow transmitter of the heat effects which deteriorate optical

Intages The 9" reflector at the right is far heavier -700 nounds. Here the only desug was to

Peterson and his portable mounting

Friend's semi-portable mounting

wheel the telescope no farther than out of a garage and a few feet distant on solid paths from H Friend, 40 Cooper St., Torrington, Conn , is the maker of this instru ment. The tube is square and built of angles and welded bands-very rigid Where a mirror is in the open, as this one is, a pair of cloth sleeves may be slipped temporarily over the ends-say, if your neighbor turnon a bright light nearby, for stray light makes trouble. This particular telescope haa Telechron motor drive in right ascension but the beginner may safely forget this refinement However, he may well study the cleanness of this piece of workmanship

TELESCOPTICS

(Continued from preceding page)

8 or 10 degree, plate glass prism Alan (see, "ATMA" p 320, a cadet at the United States Military Academy, West Point, N Y, in rummaging round the pre viously unused but recently rehabilitated observatory there, ran across the item shown in Figure 6, an old polarizing diagonal of considerable value, and at our invitation he describes it as follows.

"A diagonal employing the principle of polarization by reflection to cut the Suns light and heat down to a minimum without cutting the aperture (see Bell, "The Telescope", pp. 167-8) gives beautiful colorless views of the Sun The following is a descrip

Figure 6: The polarizing diagonal

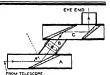

Figure 7: A longitudinal section

tion of such a diagonal (probably made by Alvan (lark about 1880) as used on a 12 refractor of 180" focal length at full aper-

"The construction of this diagonal is very imple. It consists essentially of three wedge (Herschel) prising, two of which are so mounted that the incident and reflected rays to each make angles of about 57 degrees with the normal to the reflecting our faces and thus are plane-polarized. The third wedge is intended to increase the available hghi range and to get a favorable observing position, and is mounted just in front of the eyepiece like an ordinary diagonal. Figure 7 shows the arrangement schematically, and Figure 8 as it appears in use. The tubes of the diagonal are of brass, soldered at the necessary angle. The two separate parts of the diagonal—the lower part A, (Figure 7) carrying one prism and attaching to the 'scope, and the upper part C carrying two prisms and the eyepiece—rotate with respect to each other about the short connecting tube B. This rotates the planes of polarization and thus controls the amount of light

\$8.50

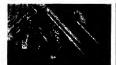

Figure 8: Diagonal on 12" refractor

passed on to the eyepiece and eye
"For minimum light," Gee continues,
"tube C would be perpendicular to tube
A, as shown in Figure 6; for maximum
light they would be parallel, as shown in
Figure 7.

The wedge prisms in this particular diagonal are mounted against soldered shoulders in separate pieces of tubing that slide into the soldered tubes forming the angle. This simplifies construction and allows removal for cleaning.

"The angle the wedges must make with the incident ray is a function of the index of infraction of the glass used. The equation, tangent $\theta = \mu$, where $\theta =$ the angle between incident ray and normal, and $\mu =$

Figure 9: The diagonal disserted

index of refraction, gives the exact value of the angle. For ordinary glass (μ =1.55, approx) the angle is 57°. As all the incident rays are not parallel, anyway, this close enough for most conditions. However, if a particularly light or dense glass used, the cauct angle should be calculated.

"Silvered surfaces or the like will not polarize by refection, although colored glass will Black glass can be used in place of widep grams it available, but abould be used with the litrid wedge of clear glass to discared text heat. The new polarizing materials now on the market, issually consisting of this abect that polarize by transmission, are not suitable for a diagonal. They pass the volet and deep red (and most of the heat) even when set for extinction, and thus are but little superior to any colored filter. Nicol prisms will work if available but are far toe expensive size which is a suitable prism and the superior to any colored filter. Nicol prisms will work if available but are far toe expensive.

"The biggest advantage of this type of diagonal lies in the fact that it cuts down the light (and heat) without cutting the aperture and without coloring the image. No colored glasses are needed. The Sun appears perfectly white and can be rigidly controlled in brilliance simply by rotating one tube with respect to the other. The difficulties of construction should not be great, the optical surfaces representing most of the work. If used on a reflector one of the wedges mounted at the required angle could well replace the main diagonal, the other being mounted before the eyepiece. The beautiful views that such a set-up gives of the 'rice graine', spots, and faculae on the Sun surely make it worth considering."

TRADE MARKS AND UNFAIR COMPETITION

By ORSON D. MUNN

A TRADE MARK is an intangible asset of a business, yet its actual value may grow so large that it becomes the very foundation on which depends the whole structure of the business Because of this fact, every business man should have available such information on trade marks as will enable him to judge with a fair degree of accuracy the desirability of any mark which he may be considering.

Here, in one handy volume, written in non-legal terms, is a simple yet comprehensive interpretation of the Federal statutes and the body of common law relating to trade marks and unfair competition.

PAPER NICATIVES, by C. W. Gibbs, A.R.P.S., is a 24-page treatize on the making of prints and enlargements by the paper negative process. Mr. Gibbs combines his extensive technical background with a wide reputation as a pictorialist of many years standing, in this highly informative and thoroughly practical work. C. W. Gibbs, 1775 Broadway, New York, New York,—50 cents.

SOUTH BEND 9-INCH PRECISION LATHER, Catalog 46 B, is a 32-page booklet printed in two colors and presenting more than 150 illustrations showing the different types of this new lathe, together with its important features and applications. South Bend Lathe Works, South Bend, Indian.—Grafts.

LEGAL HIGH-LIGHTS

Patent, Trade Mark, and Related Legal Proceedings That May Have a Direct Effect on Your Business

By ORSON D. MUNN, Litt.B., LL.B., Sc.D.

New York Bar Editor, Scientific American

RETURN MATCH

THE maxim "It at first you don't succeed, by you have been a try, try again does not supply to patent longation." It is man sout first by a patenter against the manufacturer of an article, it is decided that the patent is mysdid or not infringed by the article in question, the patenter cannot rehitigate the same question as suit against a customer of the manufacturer charging that the same article infringes the patent.

This principle was recognized by the United States Supreme Court many years ago in a suit in which an injunction was granted against a patenter restraining him from sung the customer of a manufacturer after it had already been determined in a prior suit that the manufacturer did not infringe the patent in question.

More recently the pracuple was reiterated by the Curcuit Court of Appeals for the Yourth Circuit ma suit in which the Court held that a parience was copped from charging that the customers of a manufacture were ultimage the patient in suit when it had been determined in a prior suit against the manufacturer that the articles produced fringe the patient. In this connection the Court stated.

"In such case we think that the patentice is estopped by the judgment in favor of the manifacturer from recovering damages on account of infringement from persons who have purchased from the manifacturer the articles which are alleged to infringe but which in the judgment have been held not to infringe."

FOREIGN INVENTION

WHERE a patent is obtained in the United States by a non-resident who developed the invention abroad, the question frequently arises as to the date of invention to which the non-resident inventor is entitled. In other words, under our patent law, is the non-resident inventor entitled to the date on which be conceived, developed and reduced the invention to practice abroad, or is he limited to the date on which he first introduced the invention into the United States? Arbitrary and illogical as it may seem, it nevertheless is a fact that, if the question arises in a proceeding between the non-resident inventor and an infringer owning a patent or a patent application covering the same invention, the non-resident is only entitled to prove the date on which he first introduced the invention into the United States, whereas, on the other hand, if the question should arise in a suit brought by the non-resident against a person who

does not own a United States patent or patent application, the non-resident is entitled to prove his date of conception and reduction to practice abroad.

This is illustrated by a decision of the United States Supreme Court in a suit for patent infringement brought by a resident and citizen of Japan against an American company. One of the patents in suit was applied for in the United States in January, 1922. It was proved by the American com pany that it had used the invention covered by the patent in commercial operations since June, 1921, almost a year prior to the filing of the patent application. However, the American company did not obtain a patent on the invention. It was held that under those circumstances the Japanese was permitted to prove that he had conceived and reduced the invention to practice in Japan in 1919 which was prior to the commercial

use by the American company The Court pointed out that if the Amer ican company had obtained a patent in the United States the Japanese would have been precluded, under the American patent law, from proving his dates of conception and reduction to practice in Japan and would have been limited to the filing date in the United States as his date of invention. Under those circumstances, the patent would have been invalid because of knowledge and use in the United States prior to the proved date of invention by the Japanese. This rather arbitrary distinction as to the rights of a non-resident inventor against an American patentce on the one hand and against an American who does not own a patent on the other hand places a penalty on an American who does not obtain a patent on an invention. The Supreme Court recognized the arbitrary character of this distinction but said that it could only be corrected by legislative action since the courts were bound by the patent law as enacted by Congress

In this connection the Court stated:
"We have no way of knowing whether the
discrimination results from inadvertence or
from some undisclosed legislative policy,
but, in order to redress the disadvantage
under which one in the petitioner's situation suffers, we should have to read into the
law words which plainly are missing. We
cannot thus rewrite the statute."

VINYL RESIN

WHEN does the substitution of one material for another constitute invention? Ordinarily the substitution of one material having known characteristics for another material having similar characterlatica does not amount to invention with though improved results might be obtained. However, where the substitution one material for another produces a new and unexpected result or where it solves a problem of long standing in the art it sheld that the substitution constitutes inven-

The principles of law set forth above are relatively simple but the application of the principles to any particular set of facts is quite difficult. The difficulty presented in such cases is illustrated by a recent suit brought against the Commissioner of Patents to compel him to issue a patent for an improved package or container. The package consisted of a metal container havng a coating or lining formed of vinyl resin for the purpose of protecting food products packed therein Other coatings or lining materials had been used on metal containers and it was argued by the Commissioner of Patents that the substitution of the vinyl resin costing for other types of coatings constituted a mere substitution of materials and did not amount to invention.

The Court found, however, that for many years it had been recognized that it was desirable to coat metal containers for food products with some type of material that would protect the food product from the action of the metal However, no satisfactory coating material had been developed for metal foil used in packing cheese or for metal containers for beverages. The Court found further that the use of a vinyl resin coating material for these purposes solved the problems of the prior art and provided a satisfactory package that could be used with all types of food products. The fact that the substitution of one material for another resulted in solving a problem of long standing in the art was considered by the Court to be proof of the fact that the vention and warranted the granting of a patent.

PERSONAL PERFORMANCE

A MUSICIAN or other interpretive artist may control the use to which electrical transcriptions of his renditions may be applied. This is illustrated by a suit brought by an orchestra leader against the proprietor of a radio station to restrain the unauthorized broadcasting of electrical transcriptions of renditions by the leader's orchestra.

The orchestra had made certain electrical recordings to be used on a specific radio program and the records contained a notice that they were to be used for that purpose only. The proprietor of the radio sistion used the recordings in connection with an inauthorized program and the leader of the orchestra filed suit to restrain such unauthorized uses.

The Court granted an injunction, holding that the renditions and interpretations of musicians were property and that the musicians had the right to restrict the use thereof. In its opinion, the Court stated:

mereion in to opinion, the claim states of the day give something to the composition that is a particularly hierarchically theirs, and to say that they aparticularly hierarchically theirs, and to say that they aparticularly hierarchically their and the properties of the composition of the composit

MANY STILL ARE NOT AWARE

that there is a companion volume to "Amateur Telescope Making."

"Amateur Telescope Making -Advanced"

N OT merely a new edi-tion of the book "Amateur Telescope Making," but a wholly different work for owners of that beginners' book who have absorbed its contents "Amateur Telescope Making - Advanced" has 57 chapters, 650 pages, 359 illustrations and over 300,-000 words, dealing with advanced mirroi technic, flat making, eyepiece work, drives, aluminizing, observatories and many other aspects of the optical hobby Published 1937.

RR

50 Years Ago in . . .

(Condensed From Issues of August, 1889)

ELECTRICUTION—"A nurderer in New York named Kemniler has been sentenced to draft, and his execution will be the first inder the newly enacted law by which electricity is substituted for the rope hanging heing abolished."

EXPOSITION.—"Nations to the Paria Exposition take great placasare in hearg carried from one end of the Machinery Place to the other on the electric rolling bridges, a general view of whether on given in our engraving. In fat, they are not indifferent, whether on foot or on this original vehicle, to traversing the 1300 feet of the collowal gallery in which are accumulated so many wonder-

of mechanics Morrover, many of the visitors, if not all of them, experience an intelligent sistantion in thinking that the microver power necessary for this aerial trip is furnashed by electricity and constitutes an interesting cample of the transmission of electrical netry to a distance—that problem which is now in a large measure wheat.

ICE WATER—"In the opinion of the editor of the Sonatory Lolanteer, there is a great edd of sentiment and many opinions regarding the use of ier water that vanish when the light of reason and experience is turned upon them. The fact is that iev water, druik showly and in moderate quantities, constitutes a healthful and invigorating drink. The assumption that need water is diagrenus, and that need tea, or need coffee, or feed lemonade is a harmless subscittin, 15 simply a delmino."

DIAMONDS—"The practical production of the diamond by artifical means has been the theme of a great deal of thought and a good many experiments, but up to this time it has elided all the efforts of the experimenter, though earline crystals closely approaching the gern have more than once been secured, while many persons still think it is merely a matter of time, and not a long one at that, when the secure will have been wenched from nature."

PATENTS—"The Supreme Court has repeatedly said that a man's right under his patent for an invention is as absolute as under a patent for lands, and no one would say that one should lose the right to his house because some one clee saw fit to take possession of it against his will."

FLIGHT—"When human ingenuity can match the preduct of nature, when it can make a machine possessing as much power and indiractive to the other of weight as that of the homing pigeon which lately five from Detroit to Buffalo (225 miles) in less than four hours, when it can so arrange and automatically shift a series of vances like shifting feathers in a hawks wings, which suspend it in the air for hours almost without apparent motion, when it can it in the air for hours almost without apparent motion, when it can solve the problem of how this same hawk drops like a bullet from the dezving height of a half mile, and checks itself inharmed above its pres, then it may learn to travel in the air."

REJUVENATION "Dr. Brown-Sequard's paper, lately communicated to the Societe de Biologie, of Paris details the remarkable fifets produced in his own person and also in several other men of advanced years, by the subcutaneous supertion of substances derived from the testical protings of the bodies of certain animals."

BORAX—"New horax works have recently been started in Salinevalley, Inyo county. California They have cighteen crystallizing tanks, each of a capacity of 1000 gallons. Three of these tanks are emptted daily, yielding about two tons of borax."

TRANSSIBERIA—"The proposed Siberian railway is to extend from St. Petersburg to Vladivostock on the Pacific Ocean, which is located nearly opposits. San Francisco, and distant therefrom about 1000 miles. Branch lines of the proposed road would extend to Pekin The new road would be about 4300 miles in length.

ELECTRICITY—"There are now in use in the United States more, than 5.50 central electric stations for light and power. There are 21,0000 are lights and 2,600,000 incondescent lamps. There were fifty-more electrical ratioways in operation in March last, of eighth via roads in process of construction. The increase of capital in electrical innestments domain 1888 was nearly \$70,000,000."

WARSIIIPS—"On August 22, proposals are to be opened at the Nay Department for five new crusters, to be built on plans copied from what are now obsolete English ships, down no peed, lacking in offensive and defensive means, not the latest and heat designs. It is to be hoped the execution of the Nay will be able to defer the award of construction until Congress meets and time is given to modify the proposals so as to substitute later and better designs."

CIGARETTES—"Observation in public places gives satisfactory evidence that the use of cigarettes is rapidly on the decline. Whether this is due to the stringent laws passed in many of the states against selling them to minors, or that smokers have come to their senses and have taken warning from their own expenses and the unanimous condemnation of smoking caparettes by the medical profession, or whether the evil practice has begun to be looked upon as a discreditable vice to be only practiced in secret, we know not, but it is certain that, as compared with the past, very few cigarettes are now smoked in public."

PHOTOGRAPHY—"Modern amateur photography . . . consists, vubstantially. in punting a camera and touching a spring it requires no study, no knowledge, no experience, no genus, no skill. Even children are now photographers, and the camera is coming to be a toy."

OUR POINT OF VIEW

Upward

WHILE a fear-ridden world is talking for onthing but war, it is truly refreshing to hear another note sounded—one that includes the word "armaunent" but with a meaning far removed from warfare. From England, the Seandmain countries, the King of Belgium, the Queen of Holland, and now from the President of our own country has come a call—a call to arms. But what a different call, for this is a call for more of removed the countries of the countri

These far-seeing people realize, as everyone must, that unless something is done, disaster will overtake the nations of the world as it has in the past We must not forget that nations are aggregates of individual beings, and until man changes himself we cannot expect nations to be very different. Aesop long ago, in the fable of the human body, pointed out a great lesson-that every one of us is dependent upon each other. When the individual himself will put into practice the fundamental principles of unselfishness and honesty, we will find in our business life and in our national life a great change; and as the individual and the nation change the international peace of the world will be assured. We will have both national and international peace and prosperity .- A. M. T.

Commerce

SOME months have passed since the liner Perus burned at her pier. Yet that disaster still may serve as an object lesson to shipbuilders throughout the world. Fire may strike any ship, large or small, if built by traditional designs and of the usual materials. And when it atrikes, sometimes there is a glassify tell of life, as was the case when the Morro Castle burned off the New Jersey coast several years ago.

As we contemplate with no little national pride the plans for upbuilding the American merchant marine (discussed) by H. Gerrish Smith on other pages of this issue) a greater pride grips us at thought of all that American designers and experts have done to make all our new ships fireproof. Fires can start on practically any of them, but will burn themselves out quickly. The principle behind the use of the newer designs and the newer materials is to insulate each partition, each bulkhead, each deck, against any spread of a blaze.

The details of the fireproof features of the Ancon and the Panama, of the Panama Railroad line, were discussed briefly in the April, 1939, issue of Scientific

Albert A. Hopkins

EDITOR, author, autiquarian, bibliophile, Dickens scholar—wide were the interests; industrious the mind, kindly, considerate, and tolerant the action of his man whom we called friend and our readers looked up to an merito. Our Assoriate Editor for 44 years until his best of the consideration of the consideration of the property of the consideration of the consider

Mr. Hopkins followed in the footsteps of his father who was also associated with Scientific American for many years. Edsting and writing came so easy to him that he found time for many other broad interests during his busy and productive life. Fame. which might have been his for the asking, held no glamor for hun, for his was that rare mentality which loves achievement for its own sake. He wrote, compiled, and edited a large number of books, at least one of which sold into the hundreds of thousands. An authority on the history of art, he collaborated with the late Edwin Howland Blashfield in editing Varsari's "Lives of the Painters." To the New York Public Library, he presented a valuable collection of 4000 mounted photographs of Italian paintings and statuary. He was one of the guiding forces in the Dickens Fellowship of New York, a former vice-president of that organization and editor of its publication, The Dickensian. He was also Director of the American Museum of Safety and editor of its official monthly publa atron.

Proponent of progress in science and the arts, and an energetic, indefatigable worker for those ideals that make men great. Mr. Hopkins achieved a unique greatness of his own, a transcendent joy in the art of living. He took the utmost from life and gave full measure in re-

We shall miss him for we were honored to call him friend.

American. The America, largest merchant vessel ever constructed in this country, will be made, in a similar manner, proof against fires. Likewise, the new construction will be featured in more than 20 combination cargo and passenger ships which are now on the stocks. These are following the lead of oil tankers built during recent years, all of which are immune to sweeping, disastrous fires

Here then, we repeat, are two sources of pride-justifiable pride-for the American people. After long years of apathy toward our merchant marine, years in which we permitted other nations to outstrip us on the seas, we have at last ceased our fumbling attempts to plan shipbuilding programs and will have a merchant fleet befitting our world position No longer may the analogy of the department store owner who delivers his orders in his competitors' delivery trucks be applied fully to us, our own bottoms will handle a much greater proportion of our export and import business than they have for many years. The second-and in some respects more important -- point is that our new ships will be the safest in the world. We have long stood with the best in general safety but have now definitely taken the lead in the development of completely fireproof ships It is to be hoped that our studies and experience may be made available to and be used by other nations so that fire at sea may some day be a thing of the past -F/D/M

Is Man Sapient?

REENTLY.A C Chek of the Manufacturers Mutual Fire Insuitance Co., tod the Sensological Society of America, Eastern Section, that the volume of Latern Section, that the volume of upward after the Santa Barbara qualke of 1925. The Californs premium alone recacled a total of \$3,000,000, By 1928, however, the premium had fallen to \$2.00,000 and by 1922 it was only \$750,000. Shortly afterward came the Long Beach Qualke ("Oh. My did we let that insurance lapse?"). Exactly the same crescula and diminuendo followed, the total qualke premium for the whole nation today being only \$1,000,000.

Now, since the least dangerous period as soon after a great quake, when earth stresses have been satisfied, and the most risky period some years later when new ones are accumulating, it sounds as though perhaps man wasn't the alto-gether intelligent gambler implied by the term Homo aspiens. An odd sidelight on entonnal effects of recent experiences is that the New England hurricane of 1938 simulated earthquake insurance! This should not be let lapse. The east, too samug about the west's quakes, is largely a seismic area, as it may someday discover to its sortow—d. G. I.

Personalities in Science

DAYTON C MILLER is Professor of playars at the Case School of Applied Science Cleveland, Ohn, Readers will result him as the scientist whose amen figured so frequently in the newspapers a dozen verificial connection with a module experiment on their diff. However, Professor Miller's special in the resets within the field of physics are far broader than either dirft and they include the velocity of light in a magnetic field the exportance of gauss. Roenigen rais, applications of the interferometer, the photographic registration of sound ways, and the quality of museud sounds.

Is there actually an ether! A century and a half ago students of science would have asserted with honest conviction that calone and phlogiston were actual entities having reality Today we know these were merely words with no reality be hand them I argely it is suspected, they required their high prestige from common and frequent use. They were burned into the mind. Half a century ago the wood other had similarly high prestige and solid standing, People took the existence of an other much for granted but it is suspected that the reason again was its common and frequent use, especially in teaching, for there never has been any really water-tight, final experi mental evidence for the existence of an ether. The concept was samply a postn late. Light had to be transmitted by some medium, hence there must be a medium Logic, But logic unsupported by experi ment often leads astray in science Is other then to turn out to be only a word like caloric and phlogiston? There is a marked human tendency to confuse names with things -to name something we think exists and then to feel sure that it exists, or even that we then understand it Thus far, anyway, science does not know whether there is an ether or not, Preponderance of evidence seems against if at present

In 1887, the famous Michelson-Moules, ether drift experiment had given no evidence that there was an ether. Subsequent repetitions his others gave puter totally the same results. Squarely on these findings Professor Einstein based his 1905 through of relativits. Thus, when Professor Miller came to repeat the Michelson-Movley experiment in 1921, 1924-20, and in 1929, it took on greath values about it through the press. After every many & acceedingly laborhous indi-

DAYTON C. MILLER

vidual measurements he came to the behef that he had isolated evidence of an ether drift, therefore of an ether

Scientists the world over awarded Professor Miller's research very close, serious attention, especially because they knew his record and personality and approved of both. The former was that of a careful, level-headed research worker who habitually kept emotional factors out of his mental processes --major part of the method of science itself. The latter was (and still is) genial, calm, quiet, sumple, impretentions, and unaltered by the award of medals and honors. Seentists knew he was not seeking merely to prove" the existence of an ether or out to "get" relativity approaches which would be motivated and therefore contrary to the method of science-but was making an experiment and observing the results. To this day these results have never been satisfactorily explained away Professor Miller does not root vehement ly for them as some might. He says calmly that the details of his work are now in the record, and that the future will prove them true or prove them wrong In this he resembles Professor Einstein who, when told of Professor Miller's findings, calmly said that if they were finally verified the theory of relativity would anto matically disappear. That is seeme

A wide sector in Professor Miller's scientific territory has had to do with sound and music and readers will recall his book, published two years ago en tifled. Sound Ways, Their Shape and Speed," a work for the popular reader.

But he is also a musician as well as a music hore. Skilfil as a flux player, he used that instrument first in his research on small the owner a collection of fluxes of all varieties, numbering no less than 1300. Chaires jade fluxes, walkingstick fluxes, a glass flux one coward by President Madson a human shinone fluxe, after made from the wing of an ergle, an East Indian nasul flux, and many other odd fluxes, also 55 modern fluxes. But he is no mere collector, be can play these fluxes and does

Professor Miller's most recent book is an illustrated, popular, anecdotal instory of electricity named "Sparks, Lightning, Cosmic Rays"

DELICATE BLADES IN A LINER'S POWER PLANT

HIGHLY skilled mechanics are needed for the intreaste job of blading the low-pressure turbunes that will be a part of the driving machinery of the great linet America, now being built as part of the program for a finer increhant marine which is discussed on page 88 of this issue. Some 15,000 of the delicate blades will be required—arranged in circular parallel rows—in the shell, or casing of this turbine. The photograph shows half the casing with semicircular rows of reaction bludes in place. Another 15,000 blades, similar to these but called impulse blades, will be fitted to the rotor which is to be nounted in this casing. The projecting rows of impulse blades, will be fitted to the rotor which is to be nounted in this casing. The projecting rows of impulse blades on the rotor will dovetail into the spaces

To man, a building is suck a familiar thing that he seldom pauses to think that its strength from sidewise directions is far below its vertical strength (against gravity). In non-seismic regions this is adequate, but in earthquake areas horizontal forces about half as strong as gravity may occur. The best answer is to provide a much heavier system of diagonal braces. This requires altering hun habit, custom, tradition—a slow process

Pluto by Ben S Hears

$\operatorname{Earthquakes}\operatorname{Need}\operatorname{Not}\operatorname{Kill}$

THERE was no warning, only a deep and terrible roar, and in four seconds the town of Pegu in Burniese India lay in ruins, destroyed by an earthquake. Before the frightened inhabitants could ruin a single step their flimsy city had buried them.

The earthquake is the swiftest and most grgantic manifestation of power ever seen on the globe. It dwarfs volcanic eruptions, hurricanes, even the most deadly of man-mide explosions such as the Halifax disaster of 1916. It may mother thousands of cubic miles of solid rock, change hundreds of miles of geography, shift mountains, rearrange rurers and harbors, create lakes or destrey them, open miles-deep cracks in the ground and grind millions of tons of rock to powder—all in the winking of an eye.

Before men can even tell which way to run it is all over-buildings are down, hundreds or thousands dead, cities in flames. The tremor in Southern California in 1933 lasted only seven seconds but killed 120 people. In San Francisco 40 seconds sufficed to start the ruin of a metropolis. In Chile a little while ago the shake went on for two minutes; 50,000 died and as many more were injured. Through the pages of history runs a red trail of blood and fire to mark where man, the luckless interloper, has gone down before the onslaught of the laboring earth. Lisbon, Messina, Port Royal, Charleston, Tokyo, Helena, Chillan-the record is jammed with tragedies. One moment a teeming city, the next a shambles, like a Sodom and Comorrah struck down by divine wrath.

Yet earthquakes are not "acts of God"

A Small Percentage Added to Building Costs for Adequate Bracing is Changing Earthquakes from a Dreaded Horror to an Interesting Phenomenon

By DAVID O. WOODBURY

at all. They are as normal as rain and far more frequent. Mother Earth twetches constantly lake a sleeping dog and cares no more for the effect than he. Sciamographs distributed throughout the world record an almost steady shiver of the ground—too minute to be felt, mostly, but proof of incessant activity below. In an average year Japan is visited by some 12,000 tremor, with other countries around the Pacific basin playing close seconds.

NOR are major quakes uncommon either. There are on the average 50 of them every year throughout the world. In Chile severe shakes occur every month or so, often accompanied by destructive seismic sea waves. Even in solid old New England there have been 350 earthquakes of major intensity since Colonial times. Earth tremors are as obedient to the law of averages as the cycles of the weather. In dangerous areas, such as Japan, Southern California, and South America, seismologists keep a continuous record of the uneasy earth and can foretell the probability of future quakes as accurately as an insurance company can predict the life expectancy of a

Earthquake disasters usually overtake

the public without warning, but scientises are rarely surprised. Seismologists in Southern California, for example, are momentarily expecting another major shake, with an intensity say great, possibly, as the one which wrecked San Prancisco in 1906. It may come tomorrow, it may not come for years. But they know that it will come sooner or later. Whether a great disaster will follow, as in Chile, depends upon where it strikes and how much protective work has been done in the meantime.

For people do not need to die when the earth shudders, nor do cities need to be trilned. The earthquake, says the scientist, is rarely destructive in itselfi. It is man's persistence in building inadequately—his refusal to eliminate the death-traps that he has deliberately exceeded from the structure a public both to face the simple engineering faces. Little by little it is convincing the people that if they must live where continents are still in the making they must realize their danger and prepare.

A long and difficult problem of education this is, and one that must be founded on an exact knowledge of earthquakes and of how and where they strike. Admittedly, protective seismology has only just begun. Fifty years of research has meant no more than a start.

Though the effects of the shuddering earth are gigante, the causes are most difficult to find. This is because they be of far down in the bowels of the earth that they can never be studied at first hand. Only the comparatively minine vibrations which reach the surface can be used to interpret what goes on underneath. Ironically, man's entire knowledge of the deep interior comes from a study of the tremos which destroy. Without them he would know luttle of the depths below a few thousand feet.

Earth has a solid crust 20 to 40 miles thick. Unlike the crust of ice on a pond it does not float on liquid material helow it, If it did, carthquake vibrations would not be transmitted as they are through the center of the globe A few miles down science pictures the pressure and temperature of the overlying rock to be so tremendous that the material is actually made plastic, like tar in a bairel. On this, geologists think, the hard outer shell slips and slides like scum in obedience to forces unknown Erosion, the gradual shrinking as the interior cools, the release of radio-active energy, the tidal pull of the Moon-any or all may be the fundamental causes, no one yet knows But the effect on top is certain. The thru hard crust on which we live is subjected to continual twisting and bending, stretching and compression, and is tortured into ridges and hollows as it tries to accommodate itself and fails. The result, as seen by the inhabitants outside, is the mighty process of mountain building.

IT takes many millions of years to create mountains from a plan Surface movements may be unperceptible within the lifetime of one man, yet in accumulated centuries they are hige. The Himalayas themse lives were presumably made that way The important fact is that the earth's crust is never allowed to result to the ore and over and over allowed to read plant intensity no rock can stand then all at once something lets go, and the fringes of whole continents may move of whole contensits may move

Eons of this abuse have ruddled the carth's crust with fissues which run down 20, 30, even 40 miles. These are known as "faults"; they do not show on the surface like knife-cuts in home-made candy, but are filled in with pulversor orek and debris and often only geologists can recognize them. The great San Andreas Fault in California is largely hidden, and is principally identified by mountain structures which have been rent asunder and moved past one another as much as 20 miles.

Mountain building is mainly vertical but the strips of land between faults are moving horizontally also, and at considerable "speed." The friction of two neighboring blocks of crust is very large and as they try to slide past each other they stick fast and cannot move. Gigantic stresses are built up and the loose top layers of sand and boulders along the fault are actually compressed and sprung out of shape as if they were made of rubber. A fence or road across a fault often shows this condition by being bent into the form of an "S" When friction can hold the pressures in cheek no longer there is a roar and a shudder and whole cubic miles of rock spring into life and jerk past each other. The forces are so huge that these "clastic rebounds" invariably overshoot the mark. The earth then jorks and jerks again till the strains are for the moment eased. This is an earthquake: no wonder, then, that luckless human witnesses and their puny buildings are often destroyed!

BUT the actual slip along a fault is not in itself the destructive element. It is the aftermath of vibration which does the harm. If all the cities in carthquake zones could be built on solid rock there would be no disasters, for the rock itself shakes only a fraction of an inch The danger lies in the deep deposits of alluvial soil which skirt the mountain walls. The loose rocks and sand are saturated with ground water and the conglomerate acts like a jelly, intensifying every earthquake vibration to hun dreds of times its original amplitude Thus the principle of resonance, which is so useful in a radio set, in carthquake country becomes the sinister devil which destroys everything in its path.

There is always a center of disturbance on a fault where the actual slip begins. It is usually miles below ground and the movement may not reach the sunface at all. But the vibrations do, and they apread out in every direction, often traveling clear through the cartin and out on the other sade. The whrations come in three disturb. parts: first, a high-frequency wave which is too fact to be felt, but which shakes the air so rapidly that

it creates the horrible roar often heard just before a quake. Next, a vibration of nuch lower frequency which rattles dishes and chandeliers but does little harm. And finally, the slow and deadly set of waves, traveling like rollers in the occan along the surface of the ground.

These are the ones that fling the trees about as if in a great wind, open and close huge cracks in the earth and send people staggering and often deathly seasek as they go. These are the ones that set the buildings rocking and topple them down on whomever is in their path,

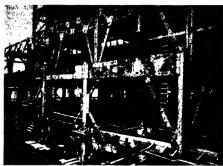

Science bases its entire knowledge of carthquakes on studies of these vibrations, transmitted through the earth and picked up by delicate seismographs hundreds or thousands of miles from the center of the disturbance. In principle the seismograph is simply a heavy weight suspended like a pendulum, holding a stylus against a piece of smoked paper. When the earth piggles the paper jiggles with it while the weight stands still and thus a record of the vibrations is scratched on the sooty paper. In highly refined modern instruments the recording is done electrically through vacuum-tube amplihers and a beam of light on photographic paper.

The successful analysis of an earthquake depends upon how accurately the center of disturbance can be located in the earth. This is a problem of triangulation in three dimensions and requires a detailed interpretation of vibration records taken simultaneously at widely separated points. A network of seismo-

area by no means safe from quakes

graphic stations is gradually being built up all over the world and a central computing headquarters has been established in Oxford, England. Records are constantly flowing to this station from everywhere and the data are correlated so as to give the position of each important earthquake as it occurs. But it is a long and

outer General Electric Company
Showing what is meant by adequate diagonal bracing against earthquakes. The
Edison Building in Los Angeles with steel frame and arc-welded seismic bracing

complicated mathematical job and sometimes years clapse before exact results on any one tremor can be published. In the United States similar work is done in Washington and St. Louis.

In localities of high earthquake danger, such as Japan and California, much more advanced measures have been taken, and well-staffed central laboratories are maintained, surrounded by a network of recording stations located with special reference to the existing faults. The work of these organizations ig gradually making it possible to predict where earthquakes will occur and to show how protection can be achieved

SEISMOLOGISTS drude the world into two narrow earthquake belts, one circling the Pacific Ocean, the other raining across. Europe and Asia from Spain to the Orient. Minor belts are found along the eastern seaboard of the United States and in the Missivsippi basin. At any point within these belts destructive quakes may occur at any time, and there is no positive assurance that they won't occur outside them also.

Disastrous tremors are uncommon in America except in the far west, although plenty of strong shakes have been record-cit the good-goal formation in the cast is the most ancient in the world and its worst shaking was over before man arrived. The middle west is almost as stable Nevertheleas, the greatest quake in American history took place in New Madrid, Missouri, in 1811, and only missed killing thousands because it happened in the wilderness. Nevth Dakota is the one state where a destructive quake has never been recorded. There is no guarantee that even that will escape for-

New York City is virtually immune,

for it is built on two deep and aged rock strata untroubled by faults Boston, on the other hand, is not far from the great Fundy Fault in the Gulf of Maine, and major shakes have occurred there. The hazard is considerable, because the whole Back Bay section of the city is built on muck pumped from the Charles River, A quake as severe as the one that struck in 1755 would probably cause severe damage and heavy loss of life. Philadelphia, Chicago, and many other large centers are similarly book on made land, which is ideal shake material, and might suffer severely even in a nunor earthquake Charleston, South Carolina, was badly damaged in 1886 by a small disturbance because it was built on poor foundations Nevertheless, the risk is considered so slight in the eastern half of the United States that almost no one ear-11cs earthquake insurance. In the whole city of New York, for instance, only a scant handful of buildings are so covered.

By long odds the greatest danger point in America is in Southern California and it is here that a typical earthquake program is being built up. The work centers around the Carnegie Institution's seismographic laboratory at Annandale, with assistance from the Coast and Geodetic Survey and the laboratories of various universities. Intensive study was begun after the San Francisco disaster but it got little support from the public till their bad fright at Long Beach in 1933. Since then the Earthquake Commission has become an accepted institution and has made use of every opportunity to urge utmost preparedness against the serious earthquake which is surely com-

Numerous seismographic stations are scattered about the state and their records of vibrations are ingeniously synchronized by photographing radio signals alongoid the tracks drawn by the tremors themselves. From these timed pute the direction from which the vibrations come and their speeds, and hence to keep informed of the slips occurring on the seven faults that cross the state. The government, also has erected a large number of monuncuts or bench marks on high ground and these are surveyed annually to indicate the general movements of the earth

WHENEVER a major earthquake occurs, most of the delicate instruments nearby are put out of commission and information has to be gathered from such random sources as the direction of fall of gravestones, the pattern of cracks in the soil and the movements of buildings and their contents. Though eyewitness accounts are highly unrehable, a postcard poll is usually taken with the hope of obtaining enough data to form reliable engineering opinions. After a serious quake one man sent in a sketch of the wandering course of the gas stove around his kitchen floor It gave the scientists an excellent picture of the earth movements at that spot in the devastation area. Recently, "strong motion" instruments have been installed around Los Angeles and hit or-miss observations are no longer so necessary

But these scientific studies, valuable as they are for the future, do not interest the citizens as much as the campaign for protection which the Earthquake Commission is also fostering. The last serious quake, at Long Beach, occurred just before six in the evening. If it had happened carlier thousands of school children would have been killed, for not a school for miles around was left undamaged and many were destroyed The public instantly clamored for advice on how to rebuild their schools so that they would not fall again, and with the help of the chambers of commerce and insurance companies, a rigid building code was worked out and passed by the Legisla-ture. Every school in California has been rebuilt or strengthened since; in Los Angeles alone it is estimated that \$150.-000,000 has been spent,

The rule for building protection is simple but often expensive, make them heavy and rigid and te them to firm foundations. A slack is destructive because its third type of vibration closely coincides with the natural period of sway of the average building, Heavy, willowy buildings especially are prone to fall in step, and their own elasticity amplifies the motion until they collapse. Large reinforced structures usually do not topple themselves but send tons of ornamentation in a deadly shower to the street. Property owners are warred not to decorate their buildings with anything that can be shaked noose Civil engineers are

EARTHQUAKE RISK IN CALIFORNIA

that question with any definiteness. A great shock may come soon, or within a decade, or not till after more than a decade. But it will come

I have been asked what I would do in the circumstances and I have answered that I would try to do the sensible thing I would see to it that my house was reasonably well tied together so that my family might sleep and live in security, and I would endeavor to arouse public interest in demanding that school buildings, stores and other structures were made safe also against wreck and fire hazard. And I would take out earthquake insurance

San Diego District San Diego and Los Angeles have so much in common in their earthquake history, it might at first sight seem appropriate to describe as one province the whole coastal plain, together metal-moniquant ranges that rise from the same of the same

A prophecy shich caused a rumpus, and its happy aftermath, When, in Docember, 1923, the nord seismologist Prof. Bailey Willis, of Sanford Unnersty, published in the Bulletin of the Sessmological Society of America the warning in the top two lines of the reproduction above, and the advice in the succeeding seven lines, incensed real estate men rushed to the head of Sunford University and (unsuccessfully) demanded recantation or discharge. Ten years later came the first major quake, Long Beach (Prof. Willis predicts another), and this made it possible for science again a long-denied hearing. A joint report of science and business (see below) was issued and and buildings were begun. Before buildings an hea altered, human traits must be altered—the bagger take.

To the Public:

In response to official requests from many representative technical and covic organizations, the Joint Technical Committee on Earthquake Proceetion was organized after the earthquake of March 10,1933, to consider ways and means of minimizing loss of life and property damage in the event of another earthquake of equal or greater intensity.

We now present to you, in the form of this summarized report, our belief as to the estimic hazard in this region and our opinion as to the proper shalince between the degree of protection to be afforded life and property and the cost of providing such protection.

We sincerely hope that the lessons of the Long Beach carefulake will not be forgotten as were the lessons which should have been fixed indelibly in the minds of all by the earthquakes of the past

JOINT TECHNICAL COMMITTEE ON EARTHQUAKE PROTECTION

bent a Milerk

asked to design the columns and foundations of new structures so rigidly that their natural period of vibration will be much faster than the earthquake's tremor. Buildings of this kind in Tokyo came through the holocaust almost untouched, but in Chile whole cities built of spineless adobe and brick were ground to powder, the inhabitants beneath Small homes of wood are unusually sturdy for their weight and rarely become death traps. They may be thrown sakew on their foundations but are likely to remain in one piece. As for personal conduct during an earthquake, say the scientists, the first requisite is to avoid panic. The victims are hiely to be the people who rush screaming to the street only to be crushed by falling debris. The safest place when the shake begins is a solid arched doorway or an inside corner of a room that is well braced. Most natives of California and other danger spots know this, but by no means all of them practice what they know when the horror begins.

An important point to remember is that a severe earthquake is aure to be followed by after-shocks, some of them nearly as severe as the original. People who have dashed into the ruins to save victims are often caught by the toppling of huildings weakened but still standing. Thousands in Chillán met their death in this way.

OPEN flat spaces are usually the safeat, for trarely does the ground "open and awallow men up," as it was reported to have done in San Francisco. But open spaces in the hearts of cities are to be matrixed. In the Tokyo quake 40,000 homeless people were herded by the Chief of Police into a broad park especially maintained for this emergency, thruging with them what few belongings they could snatch from the ruins. Within a few hours they were surrounded by flames, their tinder-dry baskets of clothing caught fire and they were incinerated to a man. The Chief of Police committed harskiri that same night, from remores.

In many earthquake countries people firmly believe that shakes do not come without warning. There is still a dogged faith in signs such as "earthquake weather." Seismologists find some justification for this but warn that actual predictions of time and place are surely the work of charlatans. In Japan, sometimes, low barometric pressure and high winds precede a quake, If there is any connection it is because the earth is in so critical a state that wind pressure against the mountain walls is enough of a "trigger force" to set the quake in motion. Occasionally, a few minutes or hours before a tremor, the land will begin to tilt slowly, but quite as often the land does not tilt, nor does the weather give any sign.

Far better than believing in signs is to work for preparedness. The responsibility for this lies mainly with the city governments, which must learn to face the menace of earthquakes regardless of civic pride. To let quake protection lag is misplaced economy; worse, it is an open invitation to disaster. Nor is a thoroughgoing program of protection prohibitive. As the noted engineer, R. R. Martel, said in addressing a Los Angeles meeting recently: "iff you will put only 10 percent more into the cost of your buildings, the chamber of commerce can adopt the slogan: 'Come to California to enjoy the next earthquake.'

TINTED LENSES

Sun Glasses Should Give Adequate Protection Yet Maximum Visibility . . . Objective is to Eliminate Rays Which Do Not Contribute to Seeing

Euron's Norts, Increasingly nule use a unglasses to eliminate glare, especially jor sports and automobile driving, makes necessary a utaring that only certain types and colors will gue the protection that is sought, in the following article are summarised the reasons for tecaing such glasses, what they must do to be effective, and the types that nill be most effective for use nith normal eyes.

TIKE other organs of the body, the Jeyes have had a difficult time keeping pace with the rapid strides of civilization. We have turned night into day, giving the eyes little rest from the continuous bombardment of light, Although the eyes are about as adaptable as any other organ, they have a great variation in sensitivity. The deposit of pigment in the choroid, retina, and it is is as variable as are the human races, yet has a definite relationship to a person's tolerance of light. By adding pigment to the eye in the form of a tinted lens, the enhanced sensitivity of the nervous conducting mechanism of the eye is allayed There are many pathologic and psychogenic states which respond to an absorption lens of the proper pre-cription There are numbers of tinted lenses on the market, many of which are offered without any pretense of -cientific co ordination with the eve.

The normal eye soes primarily with

the yellow and yellow green components of the spectral light—the most humanospari of the spectral mand the one in sharpest focus in clear words when in exact focus for the yellow, the eye is slightly out of focus for the extremes is slightly out of focus for the extremes processing the spectram, the red and violet. Docomfort may result from sharp focusing of either of those extreme rays on the sens-tive layer of the retina and a tinted lens of the neutral type may remove these rays entirely of diffuse them. A neutral type is one which absorbs equal proportions of all colors of light, as opposed to selective absorption of certain radiations.

PERSONS with normal eyes who wear absorption leaves for summer glarer usually more confortable with one of the greensh types of optically ground and polished leaves whose properties are definitely established and the three messes of which are held within close limits. Since the maximum of the visual response is in the yellow and yellow green portion of the visible spectrum, a lens which transmist these radiations will give the unitoot that may be expected in visibility with as little light loss as is possible with adequate protection.

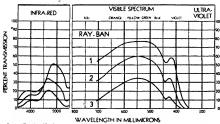

A few types of these glasses are not able for their elimination of both the ultra-violet and infra-red radiations, neither of which contributes to seeing. The dangers of these two radiations are well known in industry and they are

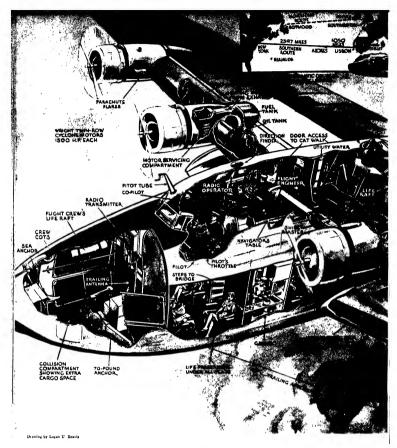

suspected of contributing to several occular diseases but their exact effect in sunlight is still a subject of study. Infraed radiation produces heat and one is warned by the burning sensation felt in the eyes Most of the illitraviolet radiations are helieved to be stopped in the cornea and crystalline lens, but any effect of them is the more misdious because the reaction is not felt for house.

Yellow-green and blue-green glasses appear to merese visability by bright-ness-contast, due to the climination of seattered light of short wavelengths, just as a photographer obtains fine pre-tures of clouds and distant scene by brotographer gets sharp photographes gets sharp photographs of enormous stretches of country by using a fifter which excludes all but the inflar red rays. All those devices function large-light scattered by the moving effect of short-wave light scattered by the intervening atmosphere.

The various tints of glasses on the market result from the kind of oxides added to the glass-forming constituent, usually a soda-lime batch, Cobalt oxide produces a blue glass, chrome and uranium oxides, green glass, gold oxide, ruby, silver oxide, yellow, manganese oxide, pink or violet, and cerium oxide, brown All of them absorb different portions of the spectrum. Amethyst glasses have a strong absorption in the blue icgion and modify colors to a great extent Amber and brown glasses absorb the blue and violet, flatten the yellows and intensify the reds, but their transmission of infra-red is high, Blue glasses of the cobalt types absorb selectively in the green, vellow, and orange-red. They also have high transmission of the infrared. Crookes glasses, brought out in 1913 by Sir William Crookes, were a great advance over previous absorption lenses. definitely absorbing both the ultra-violet and infra-red rays. Although widely prescribed today they are not so popular as formerly, due to a marked selective absorption in a narrow band of the visible spectrum, caused by the use of the rare arth, didymium, In the darker shades they absorb heavily in the region of maximum visibility

watery Bauch and Loub Light teansmission of one type of sun-glass lens, in three different shades. Note high percentage in visible, low in infra-red, and opacity to ultra-violet

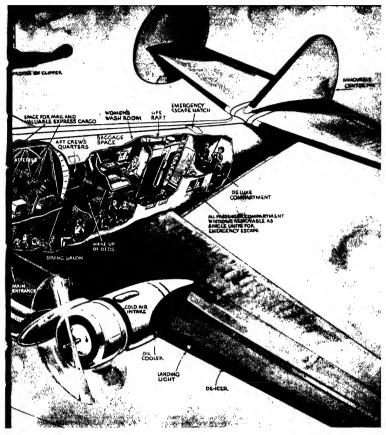

In the Transatlantic Service

WITH wings spreading 152 feet and hulb 106 feet long. Beeing Clipper ships have inaugurated transatlantic airmutal service, it is expected that, by the time this issue reaches the reader, transatlantic passenger service will have been established on regular schedule. Afteady six of these large ships have been built. Two of them are in use over the Pacific, while the other four are to be used in the Atlantic flights Our drawing shows the details of these ships, which have been designed to offer the utmost in confort and safety.

to the passenger. When used for daytime flights, 74 passengers can be carried; berths made up from triple-seat davenports will accommodate 40 passengers for night flying. Sound-proofing is extensively used throughout the Clippers,

sound-proming seximisively used inroughout in the clippers, or erew quarters as well as in passenger compartments. Air conditioning assures comfortable temperatures at all times. A completely equipped galley serves hot meals while aloft. Designers of the Clippers have foreseen every possible mergency and have made privisions for insuring the safety

of passengers and crew at all times. Individual life preservers are placed under all seats; life rafts, each capable of supporting Dersons, are radily available when needed. A kite, stored above the after crew's quarters, can be used as a signaling medium in case of a forced landing. Complete fire-fighting equipment is provided.

The inset map at the top of the drawing shows the two rought of the top of the drawing shows the two forces. It is possible, however, that, due to weather conditions and the desirability of taking advantage of favoring winds, deviations from direct courses will be a matter of routine when transatlantic flights are on regular schedule. In fact, on one of the first mall flights, the Yankee Clipper, first of the ships to fly the Atlantic, made a 300-mile detour to the south of her normal course when adverse winds were encountered. This detour made possible a stop at Bermuda.

More technical details of the Boeing-314, as ships of this type are known before they are christened, will be found in issues of Scientific American for July 1938 and May 1939. As is usual in the design and construction of new plane types, changes have been introduced as work progressed and it was found that such changes would be advantageous for one reason or another. For example, early plans for the Clippers did not call for the immovable center fin of the tail assembly. In fact, test flights were made without it and it was not m-stalled until experience indicated that it would be desirable.

McDonald Observatory

THERE is no more successful example of human co-peration than is found in astronous. Here, at least, the rule of reason prevails. Our political, national, and racial differences, however important, have really very little significance beyond the limits of the Earth's atmosphere. Here we cannot act or experiment, but must be observers only but we may still be active observers, seeking eagerly for the best opportunities and the most powerful means of unestigation

Many kinds of co-operation among astronomers are an old story, such as the division of a great field of observation, such as cataloguing the stars, into parts undertaken by different observatories; and the continual exchange of information, published and often unpublished, is the very life-blood of our growing knowledge. The smaller institutions, in particular-as the writer of these lines has abundant reason to acknowledge with gratitude-are continually indebted to the great observatorics, which, gathering information far faster than the photographs can be worked up, are most generous in supplying material for theoretical workers clsewhere.

A new and very effective type of cooperation has just been formally inaugurated in the principal astronomical event of the past month—the dedication of the McDonald Observatory.

Forty years ago, Mr. William J. Mc-Donald, a hanker of Paris, Texas, became deeply interested in astronomy, as 1926—leaving no near relatives—he left the bulk of a considerable fortune to the regents of the University of Texas "for the purpose of aiding in erecting and equipping an astronomical observatory, to be kept and used in connection with and as a part of the University, for the study and promotion of the study of astronomical science."

When certain legal problems were settled, the University bound itself in possession of about \$800,000, and a major problem arose. This sum was enough to provide for the construction of a really great telescope, and equip it with the accessories required for modern research; but if this was done, there would be very little left to provide salaries for astronmers to observe with it. If enough endowment were set aside to provide for an adequate staff, only a telescope of moderate capacity could be built with the remainder.

Rather than suffer this limitation, it was at first planned to let the fund ac-

The Large New Observatory in Western Texas Was Made Possible by an Amateur... An Admirable Site, An Efficient Housing and a High-grade Telescope

By HENRY NORRIS RUSSELL, Ph.D. Chairman of the Department of Astronomy and Director of the Observatory at Princeton University Research Associate of the Mount Wilson Observatory of the Carnegie Institution of Washington

cumulate until it became adequate. But, at the same time, the University of Chi cago found itself facing a similar, yet currously different problem The Yerkes Observatory was rich in staff, and less so in equipment. Under the new director. Dr. Struve, a very able and enthusiastic group of young astronomers was being assembled. The great refractor of the Observatory-the largest in existencehad been built when the possibilities of great reflectors were not yet appreciated. Indeed, it was the construction, shortly afterward, of the 24-inch Yerkes reflector (the first to be equipped with a mounting conforming to modern standards of accuracy and convenience) which brought the reflecting telescope back into its own. A great reflector was badly needed to extend the equipment of the Observatory; but there was no money for it.

SOME genius realized the complementary character of these two problems -each was the solution of the other. With the enthusiastic approval of President Hutchins of Chicago, and the late President Benedict of Texas (himself an astronomer) plans were developed for a close co-operation between the two universities-culminating in a formal agreement covering a period of 30 years According to this, the University of Texas was to build the observatory and the University of Chicago to staff and operate it-equitable arrangements being made regarding running expenses, and publication of the results. This close partnership between two independent institutions-one a state university, the other privately endowed-is a novelty. and promises great things.

The next problem was to find a site for the new observatory. Fortunately, Texas is a large state, and its western portion extends into the semi-arid region where high altitudes and clear sixes may be found. After the usual extensive reconnissance, a site was chosen on Mount Locke, in the Jeff Davis Mountains, in the county of the same name, The peak 17 6800 feet above the sea, with slopes not too steep to allow a well graded road to be built to the very summit, and covered closely enough with trees to protect the ground from overheating by the Sunsappear of the steep to t

The necessary conditions of habitability are therefore met—and well met. It is a cattle country, of good-sized ranches. (This phrase has a special meaning there—one may hear a cattleman say: "Oh, he hasn't a big ranch—only 80 sections.")

The observing conditions are also excellent. The seeing is good, the air clear,
and the site as sermote from city lights
and man-made glare as could easily be
found. From the summit the view ranges
in all directions over wooded mountains
separated by tawny grass-lands, with
hardly half-a-dozen human habitations in
sight. Long before the great telescope
was erected, Struve and Elivey had proved
the advantages of its location by observations of the spectra of faint diffuse in
building and of the brightness of the
2ddiscal light, and the faint diffuse illumination of the night sky—which could
only be successfully accomplished in the
clearest and purset of skies.

The Observatory itself crowns the very summit. A glance at it—or at a picture—shows one difference from most others. The walls of the cylindrical sub-structure below the dome are pierced with many windows. This reveals a very nice piece of architectural efficiency. To get the line of vision clear of the disturbed air near the ground, the great telescope is usually mounted at a respectable height, so that the floor of the dome is as far up as the third story of an ordinary house, in all their large observatories, the space under

this floor is simply vacant. Part of it may be used for constant-temperature rooms, and other scientific purposes; but most of it resembles the huge space below the dome of the 100 inch telescope at Mt. Wilson, which was once described as "providing ample parking space for the automobiles of the mechanics and the walking-sticks of the astronomers." On Mount Locke things are different The large available space is divided by floors. and provides for a library with stacks and a main room big enough to hold 80 to 100 people-it was crowded at the conferences!-also offices for the principal members of the staff, and several small bedrooms for astronomers who come down from Yerkes for special work The permanent members of the staff have houses on spurs of the mountain a little below the summit--and the writer cannot refrain from expressing his admiration of the good judgment which has made these houses really attractive

MOUNT LOCKE is remote enough to make it necessary for the permanent observers to live on the mountain. There is no near by town, as at Pasadena or Victoria, Living in a small isolated mountain community has some inevitable disadvantages. They are far less serious than they once were-no one who has heard it will forget the story of the young son of one of the astronomers at the Lack Observatory, who lay unconscious, after a bad fall, for three hours, while the doctor summoned by telephone toiled up the steep winding road as fast as a team of good horses could take him. Even today there are some moonveniences-but they count for less when the things which can be provided to make life pleasant are available.

But all else on the mountain centers, of course, upon the great telescope—the second in the world. The 82-meh mirror is of Pyrex glass- -of very low coefficient of expansion-and has been figured with almost ideal precision. Thorough tests by the veteran observer, J. S. Plaskett, show that the deviation of its surface from the true form averages only seven ten-millionths of an inch-one thirtieth of a wavelength of visual light. The "diffusion disk" resulting from the failure of all parts of the mirror to bring the light to precisely the same focus is considerably smaller than the diffraction disk arising from the properties of the light-waves themselves so that a still more perfect adjustment of the figure would gain nothing practically.

The mechanical mounting of so large an instrument is a difficult engineering problem—the moving parts weigh 45 tons. The "cross-axis" design has been dopted—in which the principal polar axis extends between two separate piers and the telescope tube is at one side of this, counterbalanced by suitable weights on the other.

The 82-inch mirror, 12 Inches thick, after aluminizing. From left to right: H. L. Gook, director of the Wainer and Swasey Company's instrument department; C. A. Rohert Lundin, director of the optical department, who figured the mirror; Dr. John S. Plankett, director emerities of the Dominion Astrophysical Observatory, who tested it, George A. Decker, works engineer. The food ratio is f.d.

This type of mounting has the great advantage that all parts of the sky may be observed-including the pole and the southern horizon Great reflectors, with mountings of this soit, existed already at Victoria, B. C., Delaware, Ohio; and Toronto, but the new instrument has one great advantage that these lack-a coudé device for spectroscopic work. When this is in place, a plane mirror, inclined at 15 degrees, reflects the light from the telescope tube at right angles, through the hollow declination axis, to a second mirror, which sends it down the interior of the hollow polar axis. It comes out at the lower end of this at the same place. no matter to what point in the -ky the telescope is directed. The rays are received in a room maintained at constant temperature, in which very powerful spectroscopes, and so on, may be intalled.

The 100-inch mounting at Mt. Wilson was designed with an arrangement of this sort, which has proved increasingly valuable and useful; but the engineering problem of adapting this to the cross-axis type of mounting had not previously been solved. It was necessary to alter the construction of the main bearings, about which the telescope is turned to reach northern or southern stars, so that, whatever its position, the light might have an unobstructed passage The unusual position of the great counter-weight at the upper end of the polar axis rather than opposite the telescope-bearing was part of the same scheme.

The instrument has also the usual Cassegrain arrangement in which the light is reflected back by a convex mirror through a hole at the center of the great mirror, to form a large-scale mage, and an ingenious device for taking photographs at the primary focus

in the middle of the top of this main tube—thus avoiding the loss of light by reflection at a diagonal mirror. The moving platform by which the observer may reach the upper end of the instrument in any position is also very efficiently designed.

The latest methods have again bein used in the "drive." which turns the great mechanism about the polat axis to follow the stars. This is entirely electric and regulated in rate by the precise and effective vacuum-tube control devised by Dr. McMahl. It can be adjusted so as to allow for the changing effects of refaction as the stars change their altitude, and the test of actual operation.

shows that it is "practically perfect."
It would be of little value to have
even so powerful an instrument if there
were not a good program of work to be
done with it. Here Dr. Siruve—now
director of the McDonald as well as the
'Perkes Observatory—has outlined plans
which should meet the hearty approval
of all astronomers. Problems which demand the utmost light-gathering power
such as to extend the boundaries of
our knowledge of the "universe of
galaxies"—are wisely left to the 100-inch
telescope, and the 200-inch when it is
finished

But there is an immense field of work in the study of individual stars, and especially of those unusual and interesting objects which are found here and there among the faint stars. With an excellent outflet of accessories—spectrographs and the like—the McDonald telescope has laredy, before its formal dedication, revealed new and important things. Its admirable site, its excellence of mechanical and optical quality, and, above all, the skill and optical quality, and, above all, make a long career of usefulness certain.—Princeton, June 1, 1939.

Under The Nieuwe Maas

AT an outlay of approximately \$8,225, 000, Rotterdam is building a subaqueous tunnel that differs radically from other structures now in use as underwater traffic routes. This single structure, which passes beneath the Nieuwe Mass River, is designed with four passageways—one for pedestrians.

one for cyclists, and two for motor vehicles. As an engineering undertaking, the tunnel is unique in a number of particulars. Work on it is now in full swing, and some of its main sections are in advanced stages.

To appreciate why Rotterdam is thus equipping he self, one should have some understanding of the extent of this center of Holland's maritime commerce. The port is situated less than 20 miles

inland from the North Sea at a point where tributary river routes and various canals have made the harbor accessible to vast interior regions of Holland, Ger many, and Belgium. Rotterdam's social, industrial, and commercial expansion during recent decades has proloundly aftered her utra-urban traffic problems.

altered her intra-urban traffic problems. At this time, 30 percent of Rotter-dam's people, many of her foremost in dustries, and the greater part of her shipping interests are located on the south side of the stream which bisects the port from east to west. The old Willems-Bridge, built in 1878, still remains the

(cross-section of under-river part of timnel in which all three classes of traffic will be accommodated Passages for motor vehicles at (a, a); eyelists (b), and pedestrians (c)

single crossing available to pedestrains which is, and street railways. That structure is now not centrally located in relation to the most active sections on the two sides of the river, and it is over taxed at peak periods of traffic. To some activate richel has been afforded by cross-river feriuse, but these have operating dawabacks. The city authorities have for vears recognized that one or more additional perinament crossings doubt be constructed; but the question was what and would best meet the requirements. Bridges, of course, have been considered as well as tunnels by the engineers.

tous of freight in oversease commerce, and the Nieuwe Maas, now familiarly known as the New Materwax, is threaded continually by ocean-to the ail of the state of the source of the sour

there is moved by water an-

nually nearly 34,000,000 short

would halt and congest the flow of motor vehicles. A high bridge, with ample under clearance for the masts of any ships using the port, would require very long approaches in order to assure acceptable gradients for vehicles. Such a bridge would have to have a length of 25 miles, and its approaches would be too far inshore to be readily accessible to motor trucks, for example, plying hetween the docks on our side of the stream and distributing points on the other side The engineering experts, accordingly, decided in favor of a subaqueous tunnel capable of providing annually for the transit of 8,000,000 vehicles, and daily use by thousands of pedestrians and evelists.

THE route chosen for the tunnel cross-ing is some distance downstream from the Willems-Bridge, and is intended to link what is known as the Park section of the older part of the city with the Charlos area on the south side of the river, where it will have its portal close to the very busy docks. The tunuel will also serve as a link for much used motor highways leading to and from other important cities of Holland The low land on each flank of the waterway permitted the designers to keep the total length of the undertaking within approximately 4800 feet; yet the nature of the ground both on shore and in the bed of the river has presented major difficulties

The project may be subdivided into two open-cut ramp approaches; two land tunnel sections; two ventilation build-

Unstable soil in the deep trenches of the approach ramps made necessary use of large numbers of piles. Deep-well pumps are operated continuously to keep the trenches drained. Each finished ramp will be a great reinforced concrete trough

ings, one at the water's edge on each flank of the river; and a central suba-queous tunnel section, which under-runs the stream and which connects with the anderwater foundation structure of each of the ventilation buildings. The river tunnel has a length of slightly more policy of the slightly more policy of the slightly more of the tunneling, including one of the tunneling, including the substructures of the ventilation buildings, the undertaking will measure \$1.311. fore!

The land tunnel sections are heing built in deep open cuts, the foundations for the two ventilation buildings have been carried down to their prescribed depths at the shore fronts by means of pneumatic caissons, and the under-river tunnel will be assembled by what is described as the "sinking method" That is to say, each of the nine separate sections of the subaqueous tunnel is built up to a degree on shore, then floated out into the river for completion in a buoyant state and, when ready for final placing in the river, it will be towed to a point directly over its given site and sunk into a trench excavated in the river bed. The substitution of this procedure for the familiar shield-and-preumatic method of tunnel driving is because the soil of the civer bottom is too loose and sands to permit the use of compressed air unless the tunnel were carried much deeper to reach firmer subsoil Other subaqueous tunnels have been constructed in a measure along kindred lines, but even so, the Rotterdam tunnel represents some novel and very interesting departmes in mactice

THE two sections of land tunnel air designed only for the passage of motor vehicles, while the river section will provide for the passage of pedestrians, cyclists, and motor vehicles. The pedetitians and cyclists will enter and leave the river tunnel through connections leading to and from surface buildings adjoining the ventilation buildings adjoining the ventilation buildings.

Each of the nine units forming the under-river tunnel is a great reinforcedconcrete block that is perforated from end to end by four traffic passages and numerous lesser longitudinal chambers for the transmission of fresh air and the withdrawal of vitiated air. Each of these box-shaped elements has a length of slightly more than 200 feet, a width of about 81.25 feet, and an exterior height of 27.53 feet. The roadway in each of the two vehicular passages has a width between curbs of 19.7 feet-affording room for two traffic lanes; and the ceiling is 13.77 feet above the roadway. The pussageway for cyclists has a width of near-ly 16 25 feet, while the passageway for pedestrians has a width of about 14.34

To protect each of these reinforced-

A partly finished tunnel section being towed from the drydork, where it was built, to the finishing alp where it will receive the remainder of its consisted both. This yiew serves to give a good comparison of the section's size

concrete blocks from water penetration. it is to have a coating of welded steel 0.236 of an meh in thickness, covering both sides and the top and bottom sur faces. As an extra protection against corrosion, that steel is to be covered with a thin layer of concrete. The working schedule has called for the smultaneous construction of three such tunnel sections in the Municipal Building Yard at Heysche-baven When a certain stage of partial completion has been reached, the divdock is flooded, the sections are floated out into the river and towed to Waalhaven, where the rest of the work is done preparatory to sinking.

To make it possible to float the sections from the divdock and to shift them to the finishing slip, each section, after the concrete is poured to half height in the drydock, is sealed at each end with a temporary reinforced-concrete bulkhead, and closed along each side with a temporary timbered bulkhead—all the bulkheads extending high above the surface of the water and giving the section the appearance of a great rectangular harge. At the finishing shp, each floating section is completed up to full height by pouring the remainder of the concrete within complex forms, and other necessary arrangements are made to put a section in readiness for sinking. The end bulkheads of concrete will be cut through after the various sections are located in contact in the river-bed trench Wherever two sections are joined, they will be bound together by an enveloping joint of concrete-the concrete heing poured under water and within forms provided for that purpose. When all the sections are linked together beneath the surface of the river, then the intervening concrete bulkheads at the joints will be cut away, one by one, while the tunnel

sections are unwatered progressively Each section of the river tunnel will be handled by floating cranes and other floating equipment, and to give it deadweight to cause it to sink, it will be filled with water so that it can be lowered deliberately and precisely to its assigned location. When it settles in the trench it will rest on a temporary foundation con sisting of hydraulically controlled jacks which will hold it at its proper level. With that done, all depressions between the nneven bottom of the trench and the underside of the section will be filled compactly with sand jetted in under high pressure in accordance with a method recently devised. When all sections are firmly supported, the jacks will he withdrawn and the entire trench will be back-filled to the original level of the river bottom

To facilitate pedestrains and cycless using the tunnel, there will be installed in a building at each side of the river of our escalators, each of which will have a vertical travel of 55.77 feet. The because the continuental Europe not only for pleasure travel but in making the daily frip, back and forth, between the home and the place of business. The actual building of this unusual structure is being done by a group of experienced engineers and contractors, for the time being known as Maastunnel Limited. The sehiof engineer for the municipality is Mr. J. P. van Bruggen, to whom we are indebted for much of our information.

FLINT FLAKING

The Amateur Workman, as He Practices, Can Progress in Days through the Same Stages of Skill for which his Ancestors Required More Than 100,000 Years of Gradual Invention

> By C. STUART IOHNSTON Department of Anthropology, West Texas State College

Figure 1: Indians mining flint at Alibates quarry From a painting by Gustaf Sundstrom

THE art of working stone into useful implements is perhaps the most ancient of human arts li dates back to the dim dawn of civilization more than 100,000 years ago, yet it is still practiced by primitive peoples in many parts of the world. One of the outstanding differences between man and his his ability to make and use implements of one kind or another. Stone implements are in many instances the only records that we have

of early human lustory. Thus man's carliest efforts toward accomplishment are recorded in the impressionable med-

direct blow from the hammer stone

Figure 2 An accurate method of positioning and placing a blow

Figure 4: The same principle applied on a more powerful scale

rum that he has left behind-stone artifacts or "fossils of the mind." On the basis of their study the earliest phases of human history have been sub-divided. We thus speak of the Paleolithic, or the Old Stone Age, and the Neolithic, or the New Stone Age. But even prior to the Old Stone Age there must have been a time, many thousands of years ago, when man was just learning through crude efforts that stone could be roughly fashioned into a tool. Artifacts of this carly beginning are referred to as Eolitlic-the dawn of the Stone Age. After the stone ages came the Bronze Age, and this in turn was followed by the Iron Age.

The ancestors of the American Indians are thought to have migrated into the Western Hemisphere from Asia, in Neohthic time, following the Glacial Period, and, though their culture reached a high point of development in several localities, and though metals such as bronze

Figure 6: Practice soon teaches shape and size of detachable flake

and a few others were used, the Indian was essentially a stone-age man when America was discovered by the Euro-

In several world localities the technique of working stone reached the distinction of a fine art, due perhaps in part to an abundance of fine raw materials as well as to the character and inventiveness of the workman. One of these localities was centered in Denmark and parts of Scandinavia, one was in Egypt, a third was in the Pacific Coast region of the United States, and a fourth in the Great Plains region east of the Rocky Mountains, Here Folsom

Figure 3: The same principle applied with an awl on a small scale

Man made fine implements of stone, and with them hunted animals that are now long since extinct.

One of the largest and oldest quarries from which the American Indian obtained his flint is located on Alibates Creek, about 40 miles north of Amarillo, Texas. Here the flint is of a characteristic red and grey color with an even texture, and is easy to recognize even in a small arrow point found, as some have been, hundreds of miles from its source. Even Folsom Man, himself, who is known only from a certain definite type of implement that he made, obtained much of his material from this quarry. Figure 1, from a painting by G. T. Sundstrom. represents the Neolithic workman mining flint at the Alibates location. The writer is indebted also to Mr. Sundstrom for the other illustrations in this article.

After man passed the long, crude stages of the Eolithic Period we find him manufacturing the first definite implement of the Old Stone Age, and, though still rough in many ways, it was unquestionably designed for a useful

Figure 7: How pressure, blows, or both may be used when necessary

purpose. This early tool, known in the Old World but not in America, is called by the French a coup-de-poing, or hand ax. This did not usually exceed six inches in length, and when held firmly in the hand it probably was an effective instrument for many purposes.

The hand ax was made from a nodule of finit by striking off rough fakes until the core reached the desired shape. This technique is important and characteristic of Early Paleolithic time. The same technique was continued into the next epoch, but with the difference that there was a specialization toward more varied types of tools. Later, the flake itself was worked into a tool by a process known as retouching, but this was applied only to one side. The next step was an improvement and greater skill in the art of resulting. The workman became more touching. The workman became more

proficient in the use of the awl in scaling off thin flakes of flint to achieve the desired shape and edge of the tool. Eventually we find that the entire implement was retouched. Finally, it was discovered that, by the proper application of a sharp blow from a hammer stone through the aid of an awl [Figures 2, 3, 4], flakes could be detached from the core more effectively, and that it also was possible to control the process to such an extent that long slender flakes

Figure 8: How the bone awl may be used for retouching a thin flake

Figure 9: Notched hone awl used for twisting off very small bits

Figure 10: Pressure flaking with an awl against a leather protector

Figure 11: Still another method-detaching flakes with aide of awl

Figure 12: Completed, and you'll be sure your ancestor was a mechanic!

could be produced with kinic-like edges, satisfactory for use without the timeconsuming process of retouching. These steps as outlined, though apparently simple, represent nearly 100,000 years in man's advance from the Lower Paleolithic through the Upper Neolthic, and are so definite that chronology in culture can be based upon them.

Contrary to jopular opinion the method involved in making stone knives and arrow points is not a lost art. Indeed, the the methods are rather simple, although considerable skill is necessary, and the worker will find that painstaking practice is essential before he is able to produce a pleasing product. The only required tools for arrow making are an awl, either of bone or iron, a hammer (for this purpose the Indian used a sustone), and a leather pad to be used as a protection for the hand from the sharp chips of flux.

THE first step in making an arrow point or a knife, or spear point is to produce a suitable flake from the material at hand such as obsidian, flint, or glass, as shown in Figures 5 and 6. This is then further worked with the hammer and awl to the rough outline in Figure 7. Now that the flake has been worked to the approximate shape of the desired implement the next step is the process of retouching In this the flake is held firmly in the hand (Figures 8, 9, 10, 11) in such a way that, by application of pressure from the point of the awl, thin scales of flint can be chipped from the edges over the surface of the flake toward the mid-line of the flake. Thus the flake is sharpened and thinned down to the desired shape, as shown in Figure 12. After the point is thus brought gradually into shape the notches for attachment are worked into the flint in the same way. First efforts will probably be crude and of the Old Stone Age type, but continued practice should bring the new craftsman with his ancient art up to the Neolithic period in which his work will be admired by others and a source of pride to himself. His respect for ancient man is likely to expand.

Lining up an Eastman removable whipstock-

By drilling dehberately crooked oil wells instead of straight ones, a young Oklahoman has added immeasurably to the dwindling oil resources of the world. H. John Eastiman, though told by engineers that it couldn't be done, showed them how drilling on curve and slant can outsut geology, put a subternaean cork in wild and flaming wells, and, by angling out under the ocean, open up to man a use huge new reserves of petroleum, intherto counted as beyond his power to exploit.

But Fastman's methods have also opened a gusher of legal controversy. If oil can be pumped from under no-man's land, the sea, sho owns at 2 "We do," say, in a confusing chorus, the operators who finance the drilling, the sovereign states in whose coastal waters at is done, and the Navy Department, speaking for Uncle Sam. Furrous controversy and legislation has the save holdly "annexed" miles out into the sheal waters off their shores.

This new method-which Eastman calls "Controlled Directional Drilling"offers to the oil industry dazzling vistas and undreamed of skills By making holes straight, slanting, or curving at will, drillers can follow geologic formations, avoid rock structures, go through faults and under salt domes. From one derrick and top hole a driller can probe under 20 acres. This new slant hole drilling makes available deposits formerly withheld from man and greatly cheapens and makes more thorough the exploitation of known fields. Because of its underground surveying system, well operators for the first time know where their bottoms are; and, in new fields, can plan spacing and drainage in the oil sand, instead of hlundering at it from the surface.

More Oil from

By UPTON CLOSE

Where oil is found under cities, buildings, parks, and cemeteries, Eastman's process can tunnel down at an angle from far enough away to make unnecessary such projects as putting the derricks on the lawn of Oklahoma's state capitol Most sensational of results' John Eastman has given the oil undustry its first (oncluve) means of controlling wild wells and extinguishing dangerous and shockingly wasterful burning craters

Thanks to Éastman, we can get some of that 70-0d percent of the oil formerly left in the earth when wells were "through." The driller can start from any point along his casing, plug up the borrebow that point and at small expense drill slantwise right through the casing pipe to a point at which the oil sand still contains enough pressure to make he oil flow. Or he can even turn a hole tor un within and parallel to the oil beard to right and train the sand drain the sand by grav-

Mup showing wanderings of an oil well, from surface (0) to full depth

ity. Vast low-production deposits hitherto commercially inworkable, and exhausted fields, such as those in Pennsylvania and West Virginia, may now contribute the "fluid of life" for man's productive and destructive activities.

Great economies can be achieved through the Estaman method by drilling multiple holes from the same derrok. Where oil lies under shoal water the advantages of this method are enormous. At Elwood, California, piers running out 2000 feet from shore bear traveling dericks which have bored wells eight feet six inches apart on the surface and several hundred feet apart at the bottom. This field, to expensive to exploit by previous methods, has yielded 54 million barrels.

Oil men wondered how Eastman would get straight steel casing into bent holes. Eastman had been so busy he had overlooked this problem. To the surprise of all, the pipe easily bent to follow the curving hole. Natural pressure and heat helped at several thousand feet down.

Untold petrolcum resources, hitherto guarded from man by the ocean, now he open to his use Much of the world's untapped ocean oil can be reached by angling out from shore. Where ocean floors shelve gradually enough to make piers or artificial islands possible, multiple curving wells drilled on Eastman principles can tap more of it. All along the shallow coast of Texas and southern California, where oil men once saw only fathom soundings, they now see dollar signs "Directional drilling" makes profitable the building of small islands many miles out in the Gulf of Mexico, It sug gests that many years can be added to the life of the world's oil resources by exploitation in the shoal waters of the Black Sca, the Caspian, the Persian Gulf, and Maracarbo, Venezuela's great mland sea. American oil geologists, according to whose past estimates we ran out of oil in 1924, in 1928, and again in 1932, will once more have to revise their predictions

FOR 5000 years, ever since the Chinese began drilling for salt with stone bits hung on hamboo ropes, men have been trying to drill holes straight. Even in America's modern oil industry this has been so nearly impossible that oil men still call a well "straight" if it is less than three degrees from the perpendicular And a three-degree deviation is enough to make a 6000-foot well find bottom anywhere within an area of seven

Short piers support rigs for drilling out under water along oil strate

CROOKED WELLS

Controlled Directional Drilling . . . Significant Advance . . . Adds to Available Oil . . . Offshore Pools Tapped From Land Rigs . . . Other Uses

acres, often drifting onto a neighboring lease or missing the oil sands entirely Wells have been so crowled as to require 800 feet more drilling—at \$10 a foot-than was necessary to reach the bottom level, others, though scientifically spaced 200 yards apart at the surface, practically interest and the surface, practically interest and the surface, and the surface of a mole indeer the lawn

Some 10 years ago, at Signal Hill, that black Golgotha of derricks at Long Beach, Cabfornia, hundreds of wells driven within each other's shadows were tangling as they went down, and owners were at law over subterraneau trespass Nearby, at Huntington Beach, nien were trying frantically with costly piers and artificial islands to tap the oil which lay deep under the sea. Young John East man, a salesman turned oil field "roughneck" by the depression, fresh from Oklahoma and unhampered by knowl edge of engineering, worked after hours on devices to make perpendicular holes To do this, he had first to make an instrument that would trace where holes were going; and, second, a tool to correct them to the perpendicular. With these devices, Eastman made it possible for the first time for an operator to tell exactly where his hole was at every foot of depth and to steer the new well constantly while it was being bored.

Steps in turning a drill hole with a knuckle joint. After the turn-out is made, the hole is reamed until large enough for regular drill bits

Then came his simple, brilliant idea, contributed to an old profession, as so often happens, by a complete nowice Why be content with correcting error? Why not precent though the ceiling of perfection into a new field? Why not apply the technique of drilling straight holes to the drilling of intentionally crooked ones—holes which would feel their way along the shart of strate, and detour around projections of hard cock?

How Alexander 1, 5000 feet deep, was killed by drilling a relief well. Explanation in text

Perhaps he could even angle out under the sea and reach those rich oil sands beyond the farthest Huntington piers!

Eastman and his young wife organized a company, put every cent into development of his tools, went broke twice in the first two years He gathered inventive young engineers and helped them to get patents in their own names, Controversies arose--- at one time he had 14 lawsuits over patents on his hands. It was tough sledding. But in 1932 he and his associates were able to set up a derrick on Huntington Beach and offer proof to a skeptical oil industry. Curving from the beach 4000 feet down and out under the sea, the well brought in more than a thousand barrels a day. One of the big California operators, the Wilshire Company, grasped the idea and took a chance. Result: A 5000-barrel well The rush was on. Ninety wells had curved away from Huntington Beach before the city and state authorities moved to bring order out

The relief well employed in killing a wild must be located a considerable distance a

of chaos and claim shares in this bounty from under the Pacific.

Two years later, a still more spectacular use of Eastman's methods took him out of Califorma and "sold" his system to the oil industry in general. This was the conquest of Texas most feared wild well," early in January, 1934, In the Conroe field near Houston, Texas, a well. known as Alexander I, had blown up from a -ubterrancan gas explosion. its derrick was demolished and the explosion formed a huge crater nearly 200 feet across and nearly as deep, boiling with oil and throwing off fumes as dangerous as

dynamite. The entire Control oil field, one of the world's largest, was imperiled. In addition, the Hamble Oil Company, owners of the adjacent leases, saw their wells failing white this one spewed forth 9000 barrels a day, which past experience showed could end only with exhaustion or conflagration.

A Humble official had beard of Fact. man's directional drilling at Huntington Beach. Eastman was called in, told that if he could hit within 50 feet of Alexander's bottom the flow could be checked Was that asking too much? 'I'll go to within 25 feet," promised Eastman, "and if I don't, you needn't pay." Humble's own people would drill. Eastman would boss. That settled, Humble made a strange deal with Alexander's owners It paid them \$300,000 for the privilege of trying to kill Alexander. If the attempt succeeded, the 15-acre lease on which Alexander stood should be Humble's, If it failed, Humble would get nothing. If

Alexander took fire after Humble started operations, the Humble company would be financially liable Since the only end to such a wild well known up to this time had been very unhappy, the boys felt they were taking Humble's 3300,000 against slight odds. No driller had ever that a bull's-eye 0.25 feet radius a mile below the surface, and in Texas slant-drilling was vall a "crays rideal".

First came the most elaborate use of fire protection technique in drilling history. A barbed wire barrier unequalled in no-man's land was built to keep sparkmaking men and animals out of the area. A battery of six boilers set at a distance sprayed steam continuously over the crater. Tanks of chemicals were ready to be turned into the steam to blanket the gas and oil lake with foam in a few seconds. Then a steel fire-shield was erected 400-odd feet from the crater's edge, the derrick put up behind it, and drilling begun. No one had bothered to chart Alexander with the new Eastman instrument as it was bored, and it was impossible now to put a cylinder down the erupting crater. Eastman surveyed neighboring wells and risked reputation, career, and money on the likelihood of the drift being similar.

CHECKING every hundred feet with his directional camera instrument (described below). Eastman began to show at his small invaible target a mile underground. He drilled straight down or 1500 feet, than on a carefully calculated ord-screw slamt. When, eight weeks later, a mile deep, he figured he was within wit feet of the bull's-eye, water under 1800 pounds pre-sare was pumped into the slant hole he was drilling. The falling of pressure showed that the water had been forced through into the bottom of Alexander 1. Within 24 hours the oil of Alexander 1. Within 25 hours the oil of Alexander 1. Within 25 hours the oil

well stopped flowing. It had been corked from the bottom with the weight of the column of water.

Eastman was "made", yet so impersonal are oil men that today the name stands for a method, not a man. Several oil men have told me that no such men as Eastman existed! Controlled drivettonal drilling, said they, was the general property of the profession. So it is! H. John Eastman presented it in detail at the World Petroleum Congress in Paris in June, 1937. in June, 1937.

Eastman has since done greater salvaging marvels than killing Alexander In January, 1935, he killed a burning crater for Sinelair in southwest Texas, boring 400 feet from the flame and ending within five feet of the hole

The top illustration shows drillers starting a survey instrument into a well. This complicated device, which the author explains, is shown in section at the "watch-face" table on which the instrument indicates the location of the drill hole at a given depth hole at a given depth hole at a given depth

at a depth of 2300 feet. The old well was sealed with concrete, the oil was pumped up through the new. In August, 1936, he extinguished a burning well at Silabee, Texas, the most spectacular conquest of a flaming "hell" in history. He struck its bore at 7000 feet depth from a surface point 800 feet from the fire. His process killed a fired well in Venezuela. He "reheved" a blown well in Roumania, making his only recorded semi-failure - his

cleid vent was below the source of presure. In most of these cases, he had to contend with failure of original drillers to survey their wella. But drillers are converted now. Recording of a well's position at every hundred feet of drill-pipe paid out is routine. The Supreme Court of California has established the legal authority of Eastman's surveying method. He and his associates are supervising jobs and instruments in the greatest oil fields of North America, the East Indies, Venezuela, the Argentine, Roumania. the Persian Gulf, Australia, and Japan. One of his praspective jobs is turning the Black Sea into an oil field—as soon as rwal empires settle the control of that region

The basis of his method is accurate knowledge of where the bit is at each hundred feet of depth, and ability to change its course. Eastman began with the primitive method, then current in the oil fields, of hanging a partly filled glass bottle of acid down the well and leaving it for 15 minutes. The said etched a mark along the fluid's top, showing the approximate slant of the bore. But it was also necessary to check the slant against true north in order to locate the well's position upon a survey chart. South African diamond miners had dangled gelatin floated compasses down their exploration wells Eastman and several young collaborators worked to combine these two ideas. At first they used an ordinary compass and fine pendulums to maintain a orizontal surface against which the angle of the casing could be photographed. Later they substituted a gyroscopic compass, which maintains true horizontal and true north undeflected by magnetized ores, lost tools, or easing pipe. This was found to be too large for best efficiency.

THE instrument that informs Eastman today is complicated, and amazingly meeligent. It can be seen at the Petroleum Industries exhibit at the New York World's Fair—a long, thun metal evhinder which contains electric batteries, a compass, a plumb bols, and a miniature camera loaded with graph him or Homm movie strip. Sealed against much and let down into the narrow darkness of a well, this device will photograph, either in single shots or at repeated intervals, the position of the compass and the angle of the wall of the well. These were the eyes that enabled Eastman to see his slanting way down to within five feet of the bottom of the faming well at Silseber, Texas,

All this must be encased in a mudtight cylinder small enough to follow a drill hit. This watch-like instrument has actually been put in a 3.5 centimeter diameter. Its length varies from five to seven feet. Eastman is trying to make it yet more spindling. Although not a professional mathematician, he has worked out little "watch face" trigonometrical graphs in the form of negatives upon which the miniature camera photographs, at one exposure, the shadow of the compass needle and an angle shadow. The driller needs no technical knowledge; a tank develops the negative and he reads the indicated graph figures and checks the result on his blue print. About 30 minutes suffices for the entire operation of dropping, raising, and reading the instrument. (Still another survey method developed by Eastman checks by the turns of the drill pipe.)

So much for the underground survey instrument, Compared with it, the tool to guide the boring bit is simple indeed. When Eastman developed it for keeping bores perpendicular, he called it the "correctional whipstock." Now it is called the "removable directional whipstock" It is a three- to ten-foot-long hard steel shield looking somewhat like a grooved banana, fatter at the bottom than at the top, and ending with a sharp point The point-at the end of perhaps several thousand feet of drill pipe--is jabbed stock is hung around a drill pipe by a collar just above the bit and is lowered and fixed in position at the angle desired. Then the drill pipe slides down through the collar, the bit follows the slanting groove and is deflected off through one side of the hole. As soon as the slant bore is long enough to guide the bit forward without help, the bit is drawn up, catches the whipstock by the collar and lifts it to the surface where it is detached until the surveying instrument shows that it is needed again for the next deflection

A second tool for bias drilling has since been developed by Eastman and his associates: the 'kinuckle' joint,' which is just a drill bit operated by universal gears and louking like a giant dentist's drill. Before lowering, it can be set to start horing at a given angle. Eastman's preference is still the whipstock.

RAMILIARITY and skill are, of course, the secrets of the successful use of these instruments. You have to know how they behave in different strata and at different algels. You must know that up to a certain speed of revolution the bit drifts right, and beyond that it drifts left, and that it tups and piecres at a right angle through hard, alanting strata—unless the slant is too great when, on the contrary, it slips along it and leads off in the other direction. And there are a thousand other tricks.

Before Eastman came along, no state or nation had much reason to be concerned with submarine oil rights. But his discoveries have produced controversy and melodrama which are national now, will perhaps be international tomorrow.

Soon after the California gold rush, a community of Spiritualias settled on the Californian coast south of Santa Barbara, and named their haven "Summerland"—their word for the world after death, for Paradiae. Their placid beach was occasionally soiled by oil seepage, recognized by members from Pennsylvania where petroleum exploitation had begun. Scruples about tampering with Mother Earth were eventually overcome through the assurance of friendly ectoplasms. "Spiritus" guided fife enterprise of the com-

munity's Colonel Wayne Darling in putting the first oil well in the world through ocean water in 1896.

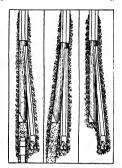

It, and succeeding wells, out as far as 1000 feet from the mark, became California's Eighth Wender of the World They were more successful as tourists attractions than as money-makers, and the contury, hard-hosted "back too fit the contury, hard-hosted "back too fit the contury, hard-hosted "back too fit the contury, hard-hosted "back to fit the contury, which successful to the contury, which catter of the other world and destroyed the character of the community. Wildcatters exited upon the under-water drilling idea and applied it in the rish fields farther down the coast at Huntington and El-

Then came Eastman, at Long Beach, pioneering with his curves out under the ocean floor The local politicians, who had thought no more of oil under the sea than of gold on the moon, became excited over wells put out into the harbor from Ford's and Standard Oil's waterfront fills. The city had granted the waterfront sites for factory and dock space -not for oil wells. This case is still in the courts Next, the California State Senate, led by Culbert L. Olson, accused corporations of taking untold wealth from state domain without benefit to the people. Two-linndred-odd wells are drawing oil for 80 corporations from under six miles of the state's 1000 mile coastline. The wells have cost twenty million dol-

lars, and have paid the state eight million in royalties.

California drew these royalties from underwater wells, claiming the ocean oil fields as state domain. Oh no, suddenly said the United States Navy, in the person of its Inspector of Petroleum Reserves. Commander William J. Greenman. How can corporation, municipality, or state claim ownership of the sea and what lies under it beyond low tide? All this is "open territory," belonging neither to state nor corporation, but to any power able to annex it. And only the United States can "annex"-individual states cannot. So the Navy, in-deadly earnest because naval oil reserves on the West Coast are inadequate, for strategic reasons supports the Hobbs Bill, which would declare these submarine oil lands to be the property of the United States

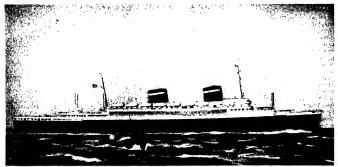

Above are shown three uses for the removable whip-stock—the first to deflect the drill bit past a lost tool, the second to straighten a hole, and the third to hend a bole. At right: Two widely separated wells directed into the same oil stratum

and, therefore, subject to the Navy's ad-

But corporation lawyers and chambers of commerce object bitterly. So does Texas because, alone of the states, it entered the Union not as a territory but as a sovereign nation. The Legislature of Louisiana, a tough state with the richest off-shore oil shelf of all, has already "annexed" as far out as 27 miles. Little Delaware, thinking of sca-water chemicals. has annexed out to 14 miles. Answering California's clargon call, state's righters have gone trooping to Washington with a cohort of harbor-masters in the van. The battle cry they shout is this: "If the Federal Government can preempt oil lands under the sea, by the same token it can possess or abolish the works and jurisdiction of every state or jointly controlled port authority in the union." It is a fantastic and also serious tangle-and also further proof of the profound sig-nificance of John Eastman's discoveries to a world that, for war or peace, cannot live without oil.

To be ready for transutlantic service in the spring of 1940, the America is the most important unit thus far in the United States Government's program for the construction of 500 American merchant ships in the next ten years, or 50 per year

WE BUILD MORE SHIPS

PASSAGE by Congress of the Merchant Marine Act of 1936 and of the amendments thereto, in 1938, evidences the determination of Congress to continue the policy adopted in the Shipping Act of 1916 and in the Merchant Marine Acts of 1920 and 1928 to carry a substantial percentage of our goods in foreign trade in our own ships, and to build up and maintain a merchant marine for both our foreign and domestic trade adequate for our national security and for our economic self-sufficiency

The preamble to the Merchant Marine Act of 1936 varies somewhat from that in the Acts of earlier years by specifying that we should earry a substantial portion of our water-boin eforcign commerce in our own ships whereas the previous Acts mandated that we should earry the greater part. The Act of 1936 provides for a direct subsidy to the steamship operator both in the building and operation of ships as against an indirect system in the Act of 1928.

The new Act requires that the Maritime Commission created under it should make a thorough survey to determine what additions and replacements of vessels are required to carry forward the national policy of the Act, and to study, perfect, and adopt a long-range program for replacements and additions to the American merchant marine; and, in the event that such additions are not provided by private operators, the Commission is different to complete its longThe American Merchant Marine Begins Extensive, Orderly Expansion... Important for Our Economic Self-Sufficiency and National Security

By H. GERRISH SMITH
President, National Council of American Shiphuildera

range program by the construction of vessels for its own account for charter, and ultimate sale if possible, to private interests.

The purpose of the Act is evidently to foster the development of American shipping under private ownership and operation if practicable, but it is quite clear that its purpose in any event is to develop an American merchant marine whicher this can be done through private ownership and operation or not. A reading of the Act abould convince anyone of the many difficulties involved in the development of American slupping under private operation, but the Act has not yet been sufficiently long in operation to determine what the final outcome may

A BRIEF study of our present-day American shipping will show that, with the exception of the few vessels built under the provisions of the Merchant Marine Act of 1928, the vessels in our general passenger- and cargocarrying trade are mostly wartime-built and have, therefore, reached the age of obsolescence It will show further that, in the foreign earrying trade, the United States is faced with the inevitable decision of putting new ships into our foreign trade services or of very soon withdrawing from these services altogether.

It is true that the foreign trade of the United States is far less than it was in the boom years of 1928 and 1929, but its value for 1938 was still appreximate by \$5,000,000,000, and it will undoubtedly continue to be of such volume as to be an important factor in our economic prosperity. Its preservation and development still require a substantial parties pation in its carriage in our own ships.

At the present time, less than 30 percent of our commodities in foreign waterborne trade is carried in vessels under the American flag, while the percentage of the carriage abroad of the American traveling public in our own vessels is about the same.

The Maritime Commission has heeded the mandate in the Act of 1936 to provide for a replacement program so that

new vessels are now off the drawing boards and are under construction in the private shipyards of the United States. Sixty-six scagoing vessels are building, 46 of them for Maritime Commission account and 20 for private owners, In this group are 40 vessels for the carriage of cargo; 13 of the combination type for the carriage of both passengers and cargo; one of the passenger type to supplement the Manhattan and I ashington now in transatlantic service; and 12 high-speed vessels for the carriage of oil All of these vessels are designed to meet the requirements of auxiliaries for national defense. The passenger vessel, to be named the America, is the largest commercial vessel ever constructed in the United States and should be ready for service in 1940

It is gratifying to know that the greater part of those vessels building for Maritime Commission account have already been allocated to existing privately operated, foreign-trans services to take the place of obsolescent vessels

A PROBLEM of great importance which has not yet been definitely solved and may require further amendments to the Act of 1936 in the disposition of old vessels now in service when new vessels take their place in operation. It is important that such vessels, when removed, should not be allowed to enter into competition with either subsidized government lines or other established services. Legislation to cover this matter is now under consideration by Congress,

The present program of the Martume Commission, as frequently stated, is the construction of approximately 50 vessels a year over a period of years to face of necessary replacements. Such a program must have in mind wessels for both the foreign and the domestic trade. The Act of 1936 without some modification, however, does not offer much encuragement for the building of occaning years of the domestic trade.

As a result of the combined national defense program and the program of the Maritime Commission, the shippards of the United States are busy, in fact with a greater volume of construction at the present time than in any previous period of shipbuilding in the United States except during the World War. The 66 vessels now building under the Merchant Marine Act of 1936 involve an expenditure of approximately \$185,-000,000, sufficient to give an average ennual employment to approximately 50,000 American workmen over a period of two years, in which employment the shipyards and the various interests throughout the country that furnish materials and equipment share about

Notwithstanding shippard activity, there is no immediate need of any expansion of shipbuilding facilities other

Looking down on the hull of the America. Divided by 14 watertight bulkheads this ship has been called "the safest ship in the world" by Admiral Emory S. Land

than such expansion as may take place in existing operating shippards.

Much has been said recently, not only in this country but abroad, of the high cost of ships. It is true that the price of ships, like the price of other commodities, has risen materially in recent years, but the reasons are many and are easily seen.

Ship design of today is far different from what it was 20 years ago—or even ten years ago. The development of the art has brought about changes which have added to cost. Added requirements of owners for the greater expedition and safe handling of earge and for the comfort of passengers have added to cost. Government safety requirements have been greatly increased with large additions to cost. The cost of labor is

much higher than a few years ago, and the costs of materials, which reflect the higher labor rates, are also much higher. All of these added costs are almost wholly beyond the control of the shipbuilder.

American shipping in foreign trade is in competition with the shipping of other nations whose costs to build and costs to operate are less than those of American ships, and in domestic trade it is in competition with railroads, trucks, busses, pipe-lines, arplanes, and other means of transportation; and its development is faced with many difficult problems. Yet notwithstanding the problems the problems involved, American shipping is in a new era and its importance to the country is such that I have faith in its continued growth and permanence.

Prehistoric Airfoils

THE development of the hoomerang by Australan aborques marked not of the most brilliant achievements which lluminated the dun arons of paleolithic cavilization. Those primeral foresaw and put into practical service what the advanced intellects of the 20th Century are so laboriously reduceavering; the conception and application of mechanical flight, Pertinent, too, is the fact that they developed their discovery primarily for purposes of warfare, the principles of fight again are being so applied today, threatening modern civilization with annihalation.

Like many scientific discoveries which have proved to be really momentous, that of the boomerang was probably fortutious; perhaps the outcome of idle contemplation of the graceful grations of an acacia leaf or the whirling of the winged fruit of the gum tree. Whatever it was, we must concede the presence of a remarkable mental trast within those savage minds which leapt far beyond contemplation by producing from the wood of those trees a unique and deadly flying weapon.

Even in the incipient stages of tribal life, weapons of defense and offense were a necessity. There would be times when the hated enemy stood beyond the reach of thrust or parry; when the possession of a missile filled the frenzied warrior with delight. He took chances and hurled. It was then that he made his great discoveries. Some implements flew prodigious distances-far beyond the range of a round object of the same weight. Some flew straight; some curled in their flight in curious ways. Why, he did not know; but we must at least assume that he would practice strenuously in times of peace, prizing and reproducing in every detail those implements which behaved in the way he wished.

It is likely that his very crudeness of workmanship was his talisman. Soon he would notice that all implements which were of any use were more rounded on one side than on the other. But this was not the whole secret. The weapon had to be hurled in a special way so that during its flight the more rounded side always came uppermost. This was the key to the prolonged flight. The pressure above the rounded surface was less than that under the flatter surface below. Gravity was, in part at least, compensated. The savage had unwittingly discovered the principle of the cambered airfoil-a principle of aerodynamics to Aboriginal Boomerangs Were Based on Principles Only Recently Rediscovered . . . Analogous to the Helicopter . . . For Sport, Game, Protection

By ARTHUR E. OXLEY, M.A., D.Sc.

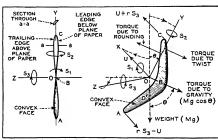

Figure 1 (left) Side elevation of boomerang immediately after throwing. Figure 2 (right): Oblique view about two seconds after projection. See text

be rediscovered untold centuries later Important as this discovery was, many uzzling problems remained to be solved. For example, those weapons which were straight, like spears, would not fly nearly as well as those which were bent near the middle-scimitar-like. In fact, Captain Cook, when he first saw boomerangs at Botany Bay, thought they were crude wooden swords. Unless the implement is bent in this way the subsequent flight is erratic and unstable. A very wide variation in the angle between the arms is permissible; from 90 to 140 degrees. In this recession of the arms we see the stabilizing principle which has been adopted in a variety of successful tailless airplanes; the backward sweep of the wings taking the place of the tailplane.

THE most remarkable feature of effective boomerang throwing lies in the skill of the thrower. The implement is thrown in a horizontal direction with as high a linear velocity as possible. At the instant of release, it is given as high a spin as possible, the implement revolving about its center of gravity O, Figures 1 and 2.

Boomerangs may be conveniently

dwided into two general classes known as the Return Type and the Non-Return Type. The first is commonly used in hunting, for bringing down birds, and so on; the second is used purely as a warwapon. In the return type the arms BA and BC are twisted about two degrees in a right-handed direction. The non-return type has an opposite and usually smaller twist. Upon this difference of twist and the method of projection depend the characteristic flights of the two types.

Whether in the most primitive of implements such twists were intentionally made is not known. More probably they were accidental insertions due to crude workmanship or they may have resulted through warping in the sun's heat. All efforts to find the true origin of the twist have proved abortive and it seems most probable that its influence was derived entirely from observational experience. The fact remains, however, that its presence introduces us to that all-important feature of mechanical flight known as the twisted-airfoil or air-screw. In the linear propulsive and rotary motions of a skilfully hurled boomerang we have all the essentials, except adjustable controls, common to the helicopter-airplane.

When throwing the retorn-type implement, it is grasped by the right hand at A and held over and to the rear of the right shoulder, the plane ABC, Figures 1 and 2, being vertical and the rounded side facing the thrower. At the instant of projection the implement proceeds with velocity U in the horizontal direction OX and rotates with spin Sabout the axis OZ which is also horizontal and at right angles to OX. We are at once confronted with the problem of a wind-mill airfoil projected in an oblique wind. The tip C lias a maximum velocity $U + rS_1$ away from the thrower; the tip A a velocity rS - U toward the thrower. where r = BA or BC. As a result, differ ential pressures are set up by both twist and rounding which cause the principal plane of the implement ABC to rotate about OX The direction of this induced spin depends partly on the twist, which, as Figures 1 and 2 show, acts in a clockwise direction as seen by the thrower, and partly on the rounding which acts in an anti-clockwise direction In all effective, that is, useful, specimens of the return type, the resultant of these spins, S., is clockwise and small, so that the plane of rotation ABC is seen by the thrower to heel slowly over to the right Immediately the plane ABC leaves the vertical, the force of gravity begins to contribute to the clockwise rotation through the torque of the component Mg cos θ acting about the center of oscillation at some point O', Figure 2

IN addition, the spinning boomerang behaves like a free gyroscope and, as such, each of the force- just namedwhich arise from the twist, the rounding. and gravity--causes the plane ABC to precess about the axis OY with a new induced spin. That part due to the twist is negative, that to the rounding positive, and that due to gravity negative. For all effective return-type implements, these component spins are such that their resultant, S, in Figures 1 and 2, is positive and small Thus, as the boomerang flies away, it is seen to heel over slowly to the right and at the same time curl gently around to the left. This combination of induced spins S, and Sa since the rounded side is kept uppermost, results in the implement's "skying" or soaring as it

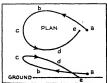

Figure 3: The simple loop flight of a becomerang thrown from point a

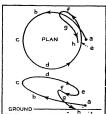

Figure 4 Double loop path of a boomerang when thrown hard

secrets to the left. The evaluation of these angular voluctures explains the tharacter of the simple hosp-flight this rated in Figure 3. The eurling to the left, due to the precession spin S_a is shown in the plan by the are above where a is the throver and c the card of the flight, The searing is shown in the region be of the elevation of the flight path. The axis of mittal spin, S_a is horizontal at a. It clumbs upwards on the thrower's left and at c it is pointing inpart and hackward

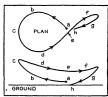

Figure 5 Another double loop, this time in the form of a figure eight

If the implement is to describe a second loop, it must be thrown much harder so that on returning over the thiower's head it has still appreciable linear velocity and spin. What will happen now depends on the position of the uxis of the original spin, S. If this is inclined forward of the thrower, the implement will start to describe a second loop like the first, eigh in Figure 4. If it points backward above the thrower, the implement will proceed to describe a reverse loop behind the thrower, and may, if its energy is sufficient, complete the figure of eight shown in Figure 5. If the energy expires during the flight, the implement will fall gracefully to earth under the influence of gravity.

Still more complicated flight-paths are possible as a result of an expert's skill. There is on record an authentic description of a flight involving five complete loops before the implement glided steeply and gracefully to earth.

In the non-return type, the war-weapon, the twist is in the opposite direction to that in the return type. It is hurled differently. At the instant of projection, the plane of rotation is inclined to the horizontal at an angle θ of from 30 to 60 degrees and the direction of projection is a few degrees "uphill" to the forward horizontal OX There is but a small torque about OX when the implement has reached a horizontal position with its rounded face uppermost. If the implement passes this position, the gravitytorque falls off (since it is proportional to $\cos \theta$) and the torques due to rounding and negative twist bring it back to the horizontal which is its stable position of flight, This very small value of S, necessarily means that the precessional spin S is very small and this is especially true if S. is large, since the precessional spin

Figure 6 Plan and elevation of

is inversely proportional to the initial spin S, about OY The flight-path of this type of boomerang is shown in Figure 6. At first the implement swerves slightly to the right along ab, and returns to a point on the straight at c Then it swerves slightly toward the left from c to d and returns again at e This sinuous path results from precessional forces which oscillate about the horizontal position of -table flight Since the rounded face of the implement is uppermost, the downward trend of the flight path is countercted and the trajectory appears practically horizontal, as viewed in side elevation, until the forward velocity is almost spent, when the implement falls, -pinning, to earth. Along such a path, the flight of the boomerang simulates closely that of the helicopter-airplane, the horizontal plane of rotation of the arms resulting in a vertical lift which adds to the levitation arising from the camber of the upper rounded surface of the arms.

Near the end of the flight, the steep angle of glide, without the slightest suggestion of stalling, is fascinating to watch. The hoomerang illustrates well those principles of mechanical flight which the modern aeronautical engineer is striving to perfect, safe descent at very steep angles combined with almost negligible landing speed. And yet the possibilities of such heavier-than-air machine-models though we may call them-were known and used in instruments of sport, livelihood, and protection not only among the primeval races of Australia, but among the savage prehistoric tribes of Central India, Ethiopia, and among the Hopis of Arizona.

A MONTHLY DIGEST

Unique Hinged Swing Spans on Bringe

TRIF completion of a reinforced concrete south of Carrels, California, constitute the last link in a series of structures, inseparable elements of Coast Highway Route 56, between Monterey and San Sumeon Its construction introduced immisual problems in heridge design.

At the site of the crossing Big Creek meanders along the bottom of a deep "It" shaped canyon. Foundation exploration in dicated that the steep, sloped canyon wallsconsisted of a badly fractive disale formation and that underlying the stream were Conducted by F. D. Mc H U G H

Lower right: Location of the arch bridge discussed in the text Above One of the arch spans, one of the half arches, and the floating span

beds of clay, sand, and gravel of reasonable bearing value for the bridge foundations. The highway alignment at this location is immediately adjacent to the sea coast and approximately 90 feet above the bed of the stream.

In selecting a structure most suitable for this stee, fundation conditions were of course an important consideration, as was also the locale with its heavy fogs, rains, and saltspray laden winds In fact, the latter consideration ruled against a type of construction suitable for an inland site. Full coinsulction of these factors led to the adoption of the reinforced concrete arch as the inost suitable type for this location.

The arch structure comprises two main arch spans 177 feet 6 inches long across the canyon, and two tied half arches of 81-foot

TEN-MAN PNEUMATIC

RECENTLY under test at Wright Field, Dayton, Ohio, has been a pneumatic life raft, developed for use with large air planes of the hombardment type when engaged in overwater flight. When inflared and placed in the water, the raft is capabile of seating 10 men, while a life line attached to the raft and extending around it will support 10 additional persons.

The pneumatic life raft ready for inflation and, right, the raft in use

The supporting structure of this raft con sists of a latex rubber bladder with a heavy rubberized duck outer cover The bottom is ol heavy rubberized duck fabric and con tains three pneumatic inflatable seats. The latex tubes are equipped with valves and manifolds for CO₂ inflation About five tion operation. The cylinders containing the CO, are attached to the raft and fed directly into the tubes. The weight of the raft when inflated is approximately 115 pounds. When folded the raft can be rolled into a bundle approximating three cubic feet of space

Four two-section metal oars make propel ling of the raft possible in the water for a considerable distance Four army canteens of water, a quantity of emergency rations, emergency signal kit with six red flares, and a syrotechnic pistol form additional equipment All of these are eneased in water proof holders

In order to repair possible panetures while afloat, an emergency pump is provided With a repair kit, this makes it possible to keep the raft affoat indefinitely When inflated, the buoyancy is such that the raft is virtually nonsinkable. It will float even if turned upside down on the water, and has been found to be considerably more stable and more easily handled than the smaller sizes

In the hombardment airplane, the rafts will be stowed in a position within easy reach of personnel Experimental testing at Wright Field having been completed, an order was placed for

a service test quantity. CATALYTIC REFINING

* ATALVOTTO ---- ! !----A routine method for the manufacture of petroleum products. Limited originally to large plants, because of the heavy investment required, catalytic refining processes now have been developed for the smaller plant. Increased production of gasoline of 2 to 8 percent is reported by the operators of the "midget" catalytic plants, together with an increase of 2 to 4 percent in octane rating of the gasoline. Similar results, with even greater increases in gasoline yield and octane rating have been reported by operators of the larger catalytic plants.

As currently operated, catalytic refining plants produce about 45 percent of 80 octangasoline the first time the crude oil is passed through the stills, making no fuel oil unless desired, and producing only gasoline, gas, gas oil, and a small amount of heavier residue. On subsequent runs through the stills, additional amounts of gasoline and other usable products are obtained. Conversion of 100 percent of the crude oil into gasoline is

physically possible under the new to huque Catalytic refining adds the action of a eatalyst to the action of heat and pressure, the physical contact of the oil with the catalyst causing a chemical reaction which converts greater portions of the oil into gasoline Refinery gases, resulting from cracking and distillation, also are subjected to catalvise processing, adding still further yields

of gasoline Catalysts orchnarily used have metallic compounds or alloys as their base. A typical catalyst is a mixture of silica and alumina. pressed into bricks Other catalysts are made of acid treated clay, containing oxides of manganese and nickel The effectiveness of the catalyst decreases very little in use and can be renewed after continued operation

A BLIGHT-RESISTANT

CHESTNUT

SEVERAL years ago the Bureau of Plant Introduction of the U.S. Department of Agriculture brought in shipments of the Chinese chestnut Castania mollissima in an effort to find a variety that would be resistant to the chestnut blight which worked such havor in the chestnut area of the United States that practically every American chestnut has been destroyed Crosses of one or more of these chestnuts were sent to the Bartlett Tree Research Laboratories, and among them was one which has grown

Blight resistant

for 20 years and has fruited for several years The nut, too, is similar to that of the American chestnut in size, quality, and sweetness Mr. Bartlett carly recognized its merits and has distributed more than a thousand oneyear-old seedlings to commercial nut growers in different sections of the United States. Because of the service rendered by Mr Bartlett in co-operating with federal agencies in the distribution of this promising cross. the chestnut has been named by government

workers the Bartlett chestnut. In some instances, our native chestnuts have sprouted for a few years, and some have even frosted but then succumbed to the blight so that it does not appear likely that a disease-resistant native chestnut will grow again in the areas originally affected by the blight -C. F Greenes arpenter

INSTRUMENT FOR

CHEMICAL ANALYSIS

BASED on established principles and de-veloped by the engineers of the Fisher Scientific Company, a new instrument has been announced for conducting qualitative and quantitative analyses in both organic and morganic industry.

The Electropode, as the compact instrument is called, employs the dropping mercury electrode system for analysis. With this ystem, a series of potentials are applied to drops of mercury as they fall through the solution being analyzed. The results are solution being analyzed plotted and the presence of each particular ion is indicated by an increase in the current at a specific voltage. The extent of the increase depends upon the ion concentration.

Another View of GERMAN AVIATION

WE have heard glowing reports of German aviation from many sources, and German bombers have been Hitler's trump card in his diplomatic or, rather, undiplomatic maneuvers. Is it just possible that the Reich's strength in the air is over-rated? Picture Post, a well informed English maga-zine, published some interesting views in this regard.

One hundred pilots a month were killed last year in the German Air Force, which is an indication of hurried training, and of weakness rather than strength.

Visitors have apparently free access to German airplane factories and are duly impressed with such facts as the production of three-engined bombers at the rate of nine a day, or single-seater fighters at the rate

Exterior of the pressure tunnel for testing airfoils and airplane models

of twelve a day But such glimpnes may be dichberately milaculard, Petture Post says. "That factory may have been building its sirplane parts for months, and other parts may have been worked on by other factories, and all might have been ready for the final assembly of aircraft the day before the visitor was slown over." The final rapid assembly might thus well be the culmination of months of relatively slow effort.

Again, in building American Paut & Whiney engines under license, the quality of the steel was so had that the crankchaft of the engine had to be strengthened, weight of the engine had to be strengthened, weight of the engine increased, and over-all efficiency lowered. It is also reported that the German-built Pratt & Whiney Waspa have to be overhauled every 35 hours, whereas in the United States overhaud is placed with the control of the time that American true will serve.

These are rumors Still, there is some reason to believe that reliability may have been sacrificed to quantity in the Nazi Air Forces, and in time of war, only that airplane counts which is capable of continued service.—4. K

MULTIPLE HANGARS

FROM time to time we have pointed out in these columns that hanger space is valuable and that hangar rent is an important item in the budget of the private plane owner. Considering the present type of conventional hangar, elaborately constructed in steel and concrete, with high roof trusses, it is obvious that hangars cost money, and that the present high rents are probably a necessity. To overcome this drawback, the Edwards Multiple Hangar has been designed to reduce the cost of airplane housing, and also to provide the owner of an "airplane garage" with housing of such flexibility that he can adjust his space to current requirements and not be tempted to speculate by erecting an expensive building which may remain half empty.

One of our illustrations shows a sevenunt hanger block. The low overall height, made possible by use of a special cantilever roof truss, is only 16 feet as compared with the 36-foot height of the egoventional hig hangars. Thus reduces the minimum area required for the landing field, since the approaches become lower. The staggering and overlapping of the hangars reduce the ground required for a number of machines to the absolute minimum. Each unit houses a single plane. The hangars can be built singly, or in blocks of two or more as desired. The privacy of each block should make an appeal to the smaller flier — A K

A HUGE PRESSURE TUNNEL

OF great interest to visions at Langle-Field as the 10-feet pressure tunnel shown in one of our photographs. To science conditions comparable with those of flight, the new 19-feet tunnel is designed to use are at a pressure of two atmospheres, the apeed of the 19-feet diameter pet will be 250 miles an hour in operating the tunnel, the operators will work inside the pressure chamber, tike the "sand hours" who drive tunnels under our rivers. Special aur locks and a decompression chamber will be provided.

The tunnel is of atecl tubular construction, with a maximum diameter of 60 feet, a length of 270 feet, and a world to 128 feet. The 34% foot propler will be driven by an 8000-horsepower electric motor. In the working chamber the large forces on arrifol or air-plane model will be recorded by automatic halances, which will give the engineers a faithful picture of what they may expect from the actual flying machine—A. K

"SMOKED" GLASSES

THE American public has declared a defleasive war on invisible rays, using for armor certain types of glass which protect the eyes by admitting visible light and stopping the invisible ultra-violet and infra-red rays. A 700 percent increase in the use of this glass since 1928, amounting to many tons, is reported by the American Optical Company.

According to latest scientific investiga-

tion, the invisible ultra-violet and infra-red rays are not necessary for seeing and in excess quantities may produce pathologic eyconditions. The protective glasses, the composition of which is responsible for their absorptive qualities, are used for outdoor wear to protect the eyes from excess light (glare of the sum) and the invisible rays.

Many years of research were required to develop efficient absorption glasses, Dr. E. D. Tillyer, the optical company's research director, stated The problem was complicated from the beginning by the difficulty of cutting out the invisible rays and maintaining at the same time a desirable transmission of the visible light rays.

Finally, after long experimentation, certain elements in pure form having ultra-violet and infrared absorptive properties were discovered. Added to hatches of glass, these clements produced glasses which transmitted light without undearable color distortion and at the same time uniformly absorbed the invisible rays.

The elements having these remarkable properties, Dr. Tillyer stated, were cerium (a rare metal resembling iron but much softer) and very carefully balanced quantities of iron compounds. To prevent color values from being distorted, he emphasized, the ratio of the iron compounds must be watched very carefully

CONQUERING THE ATLANTIC

IT is now a matter of record that Pan American Airways have crowned their many achievements by the first scheduled flights across the Atlantic, under commer-Pan American and to the Boeing Clipper (See also page 76, this issue.) The achieve-ment is all the more remarkable when we consider how brief is the chronology of transatlantic service. Scarcely twelve years ago (October 1927) the first international airmail and passenger service extending beyoud the horders of the United States was established by Aeromarine on a little 90mile airline between Key West, Florida, and Havana, Cuba. Early in 1929 Pan American Airways formulated its first plans for transatlantic operation, undertook a complete aurvey, and adopted specifications for aircraft, weather and radio services, base facilities, and so on. In 1931, the first "laboratory were made on a northern great circl route. In 1932 and 1933 there were expeditions to Greenland, and the building of the Sikorsky S-40, the first four-engined flying boat. The year 1933 saw another survey head ed by Colonel Charles A. Lindbergh. In 1935 was held the first international conference on Atlantic air travel. Then came more surveys, a larger Sikorsky, and finally, in 1938, the Yankee Clipper was constructed. Then came shake-down flights, more surveys, and, finally,

Multiple hangers for airplanes conserve space

in May 1939, the first regularly scheduled flight. To the public the establishment of progress has been very rapid, when one considers the immensity of the task.

Pan American will not be left alone in the transatlantic field. We may expect Air-France, Imperial Airways, Lufthansa all to be active. And, moreover, there will he an other American company in the field. Thus-American Export Airlines has filed with the Civil Aeronautics Authority application for a certificate of convenience and necessity covering Atlantic routes from New York or Baltimore, via Botwood, Newfoundland, to Foynes, Ireland, Horta, Azores, Biscarrosse and Marseilles, France, As soon as the latest Consolidated flying boat, shown in one of our photographs, has been approved by the Authority, three survey flights will be made. one of these being non-top from New York to Biscarrosse A strong argument in the application is the fact that the new airline will be affiliated with American Export lines, which maintains a fleet of 18 surface vessels. From five to eight of such ships are normally at sea at all times between New York and Gibralian With complete two way radio and meteorological observation services. the help to navigators will be immense. In vestment hankers have bought enough stock to finance the venture on a sound hast-

The Consolidated Model 31 Flying Boat has made successful test flights with 52 passengers and a crew of five. The Model 31 is a twin-engined flying boat, powered with Duplex-Cyclones of 2000 horsepower each The gross weight is approximately 50,000 pounds Hydraulically operated Fowler flaps extend from the hull to the ailcrons The rear portion of the hull is so designed that the tail surfaces rise high above the water, and the vertical surfaces project well below the stabilizer, which is a safeguard against spin. There will be two full decks Wing -pan is 110 feet (arrying 28 passengers, the boat will be capable of non-stop commercial service across the Atlantic.

Pan American with Boeing Clippers, against American Export with Consolidated Madel 31, will provide the competitive zest which is needed to secure maximum effort and efficiency on the part of both companies. -A. K

No-SLIP PAINT

FROM United Laboratories comes announcement of a new non-skid paint for use on stair treads, concrete floors, steel floor plates, and other places where resistance to abrasive action is desired. It is known as Armor Plate 419, made up of stainless steel flakes in varnish vehicle - Streamlining.

MOST POWERFUL AIR-COOLED ENGINE

BUILT by Wright Aeronamical Corpora-tion, and known as the Duplex-Cyclone, the most powerful air-cooled engine in the world is of the radial type with 18 cylinders arranged in two rows of nine each, and is rated at 2000 horsepower. It derives from the Double-Row Cyclone of 14 cylinders which is rated at only 1500 horsepower. Provided always that a suitable propeller can be designed to absorb its immense power ef-ficiently, this latest engine will do a great eal to increase the speed both of our trans-

backs reported, however, that the effect is

ports and of our large Army bombers I wo of the Duplex-Cyclones have already served soon lost. Making inquiries on other phases of the in a large flying boat of Consolidated Air problem, the investigators find that praccraft which has been recently test flown on the Pacific Coast with marked success and tically every rubber part requires some de-

ARTIFICIAL HEART

REMARKABLE artificial heart which can replace any animal heart for pumpme blood at its ordinary temperature of 98 degrees. Fahrenheit, through the arteries and veins has recently been perfected by Dr. Gerhard Katz, of Tulane University, This heart can, in fact, be used either for the perfusion of living organs with fluids other than blood, or for the maintenance of the circulation of an experimental animal. It can be operated at a maximum speed of 100 strokes a minute, although a lower rate is usually preferable. An air valve in the heart is opened and closed by a photo-electric cell activated by two beams from two light sonrees, which pass through the glass tube and are interrupted by the blood column. These light beams are focused by leuses in such manner that one passes through the bottom of the tube, while the other one is focused on it at any desired height

During the systole operation, the an valvis opened and the top light is dark. Air pressure then pumps the blood out of the tube into an experimental artery, for example, until the blood column reaches the beam of the bottom hight. This heam is thus al-

Above: The artificial heart perfected by Dr. Katz. Below: A closeup view of the mechanism used for research on experimental animals

lowed to penetrate the glass tube and activates the photo cell, which then closes the arrivalve and switches on the top light. The output of blood per stroke is regulated by the height at which the top light-beam passes through the glass tube. Increase or decrease in the venous blood return to the heart correspondingly clunings the ordinary rate of

This artificial lieari his been used in studying the action of arteries, velos, and kidneys, when dearbed from the animal to wheth they originally be longed. An outstanding advantage is that it can be slowed down or specific up as desired, its operation is wholly not basical It contains neither timmotion for the state of the state of the contains the state of the state of the state of the tribber. And there are no priories, because the blood which comes in contact with them sometimes becomes tow. It is the first apparative of its kind operated by use of a plin track time till.

This heart is not designed to serve as a substitute for a human heart in the prolongation of life, neather is it available for the allevation or cure of heart ailments. Arouse dugs for the treatment of heart trouble are now used practically by physicians and specialises. Artificial hearts for experimentation and research are not news, they have been used by experimentates during the list 55 years on the study of blood vissels, vitus, arteries, and their reactions.

NEW SMALLPOX VACCINE

On the heels of news of recent smallpox outbreaks in New York and Tennesse conies an aunouncement to scientists of a new smallpox vaccine which eluminates the severe scars and other inconvenient features of ordinary vaccination.

The new vaccine was developed by Drs Thomas M Rivers and R D Bard and S M W and of the Hospital of the Rockefeller In stitute for Medical Risearth in New York It is made by growing vaccine virus on a special medium consisting of minered chickembryo tisses and Tyrode's solution. Vaccinations against smallpox ordinarily are made with call (Jupit) vaccine virus.

Vaccination with the new vaccine virus should be followed, within six months to one

year, by re-vaccination with calf lymph virus. the Rockefeller scientists advise in their report to the Journal of Experimental Mediindividuals will not become sick and will not be subjected to the dangers associated with primary vaccination with calf lymph virus, but will obtain a solid and lasting imminuty to smallpox

No sear forms after the primary vaccina tion with the new vaccore virus, it is reported, if the moculation is properly made Nor is there any fever or discomfort. Following revaccination later with calf lymph virus, very few of the children had fever or other symptoms, and what sears occurred were only 'small superficial' ones. Science

ANTI-CORROSION

AN aqueous solution of alcohol is A one of the commonest auti-freeze solutions for automobiles The addition of less than I percent by weight of natrate solts, according to a recent patent, will prevent conresion of aluminum parts of cooling Systems

IT "TALKS BACK" TO YOU

THE machine shown in one of our illustrations can both "listen and "talk back ' And it a perfect mimic too In fact that's its job It "mirrors, what is said to it -sends it back as accurately as a mirror reflects your image

Looking like little more than an endless belt of narrow steel tapes wound upon small drums, this device is a voice-recording and reproducing machine that has many uses One of the first of its kind was introduced several years ago as the "voice morror," and thousands of visitors to "open houses" con thousands of visitors to "open houses ducted by the telephone company in New York State and elsewhere used it to "hiai themselves" One spoke a message into a telephone transmitter, and then heard the exact words and tones snoken back to hun through the receiver

Applied to everyday use such devices tire

Spray painting over a floor grating; no booth is necessary

vide the "voice" for the telephone company a weather forecast bureau in New York City. and in New Jersey are used to give farmers and produce dealers crop reports by tele-

In recording the voice, a moving belt of steel tape passes across the poles of an electro-magnet at a rate of about a foot a second while speech currents produce a varying magnetism on the tape. The machine will repeat the message indefinitely. The recording can be "erased" by the flick of a key, and the machine is then ready to take a new message

SPRAY PAINTING WITHOUT BOOTHS

I INIQUE facilities for spray painting which climinate painting booths re move the fire hazard, and make it practical ly impossible for operators to inhale the -pray, have just been installed in the lathe manufacturing plant of the Monarch Ma

cline Tool Company. I athes are now being painted on the assembly floor within a few feet of other operations with no walls or partitions of any kind to screen off the sprayers. Painting is done over a seven, by twelve foot grating in the

floor through which air is exhausted at the rate of 200 feet per minute. The fume-laden air is disclarged into a large welded tank located directly below the grating where a water effectively segregates the solids in the paint fumes. This precipitates a sponge rule ber-like substance which can easily and convemently be cleaned from the pit. The air is then carried off through an underground tunnel to an outside exhaust stack

Since the solids precipitated in the water are non-inflammable, the fire hazard created by the highly combistible pyroxylin which collects around the consentional spray booth, on the floor and in the exhaust system, is aliminated.

With the an suction down instead of up. and since the painter never has to hold the spray gun above his head, which would put him between the spray gun and the exhaust the operator is never in a position where he can inhale the fumes. The draft is strong enough to pull effectively into the exhaust any spray not immediately deposited on the social being painted.

FOR POLISHED PARTS

APPLIED by brush or spray gun, No-Rust Liquid V-15, recently introduced by Frost Paint & Oil Corporation, dries quickly to form a tough, non-porous film which resists abrasion, the elements, and salt water, and is recommended as protection for polished steel parts in storage or slupment. It is readily removed by wiping with kerosene or gasdine -Streamlining

VITAMIN ALPHABET

COING OUT OF STYLE

THE vitamin alphabet, that is, designation of the various vitamins by letter, is going out of style For example, if you want to be really up-to-date, you must learn to say ascorbic acid instead of vitamin C when you are referring to the substance in orange jaice for other citrus fruits, tomatoes, and other vegetables) which prevents and cures

This may be discouraging, especially if you pride yourself on having really learned the vitamin alphabet, or most of it. But the scientists who have most to say about vita-

teel tapes and recording and reproducing mechanism of the "back-talker"

mins. the nutritionists and hinchemists -- are trying their best to get the vitamins out of the alphabet They make the point that the letters did very well for names in the early days of vitamin discoveries when only a few were known and not much was known about them. Now, however, since there are about as many vitamins as letters of the alphabet. with half-a-dozen going under the name of B, it is confusing and even leads to maccuracy to call these essential food factors by letter.

Some of the vitamins have been identified cliemically and even made synthetically They have regular names, just as other chemicals have. Vitamin C is ascorbic acid Thiamin is the beriheri preventing and curing substance that once went under the name of vitainin B or B. Nicotinic acid, the stuff that is curing pellagra, is the chemical that was variously called vitamin B2, vita-min G and the P-P or pellagra preventing factor Riboflavin is another diet-essential G Recent discoveries have shown that it is necessary for the health of both man and other animals

The anti-sterility vitamin, formerly called E, 18 now known as alpha tocopherol Vitamins A and D may keep their letter names for some time, because there is not so much confusion about them as about the B vitamins Until the chemical composition of other vitamins is discovered, however, scientists favor calling them by descriptive names, not by letters .- Science Service

NEW AUTO SPRING RELIES ON RUBBER

DEVELOPMENT of a new type of automobile spring which uses three pounds of rubber and seven pounds of steel in place of the usual all-steel construction was announced recently by the B. F. Goodrich Company The new spring requires no lubrication and reduces rattles and squeaks reports Science Service.

Rubber springs have been invented and patented many times, but none has ever come into general use. The new spring gets around the difficulties of most of its predecessors

Above: Rubber springs in the front-end of a motor car. Below: One of the springs, showing how rubber is placed between a shaft and a shell and stressed in torsion

through the fact that the rubber is under compression and twisting or torsion pressure metead of being under stretch or tension When under tension, cracks develop in the surface of rubber and it soon deteriorates

The rubber surrounds a central steel shaft and is in turn surrounded by a pair of hemispherical steel shells. By making the rubber layer a little larger in diameter than the meide diameter of the steel shells before they are fastened together, the rubber is put under pressure. High pressures are applied during the curing process to bond the rubber and metal firmly. The spring is stressed in torsion by anchoring either shell or shaft to chassis and rotating the other member.

The entire arrangement takes advantage of one of rubber's most marked and most de strable characteristics, its ability to absorb and damp vibration. This has not previously been done in the springs in widest use in automohiles.

NEW PLYWOOD FINISHES

TO extend the usefulness of plywood further in modern building construction. 1 F Laucks, Inc., has presented two important new paints that offer not only decoration but fire resistance as well to plywood construction.

These two new paints are known by their trade-names, Rezitex for certified exterior plywood, and Plasterez for interior plywood walls. They have as their binder a apecial combination of synthetic resins, which as-sures perfect adhesion to the plywood, and a surface that is durable and non-brittle. Both paints are heavy bodied and will cover up small cracks and joints in the plywood

These products were originally developed for application on plywood, but since have proved themselves suitable for application on all types of surfaces-plaster, wood, metal, and wallboard. Rezitex and Plasterez both simulate plaster, stucco, or concrete finish

HOOVER DAM

N newspapers recently there has been considerable comment regarding the question of the name of the dans recently completed in the Black Canyon of the Colorado River Officially named "Hoover Dam" some yearago, its designation was changed to "Boulder Dam" about the year 1933 It now appearthat this change was never officially made for in an exchange of official correspondence recently, the United States Attorney General indicated that the name "Hoover Dam" had been legally fixed and that it was not feasible to change it Since new maps will carry the original designation. Scientific American will henceforth refer to this projest as Hoover Dam

BACTERIA AND MINE FIRES

MINE fire is sometimes extinguished A VINE tire is sometimes calling the area by blocking off and scaling the area To determine whether or not the fire is out, usts for carbon monoxide are made of the -caled atmosphere

Recent studies by the U S Bureau of Vines have shown that, under favorable conditions, unidentified bacteria or micro-organisms which inhahit waters and slindges of anthracite mines react with carbon monoxide and produce carbon dioxide. These studies show that failure to find CO in a scaled area does not prove the absence of fire as hadteris may consume the gas as fast as it is produced by the fire

PROGRESS NOTE ---TRAFFIC CHANGES. 1904 to 1937

BRITISH automobile traffic appears to be moving backwards

A survey of traffic speeds by Great Britam's minister of health reveals that in 1904, the average speed of a horse-drawn bus travcling from Swiss Cottage to Oxford Circus, in the heart of London, a distance of about four miles, was not quite nine miles an hour. In 1937, several tests indicated an average speed for the same journey by motorbus of about eight and a half miles an hour.

In 1904, the average speed on a trip from Highbury to Piccadilly, about five miles, was a little more than eight miles an hour. Today, the speed is somewhat under eight miles an hour .- Science Service.

LONDON PLANE TREES

TONDON plane trees, among the few species that can stand the smoky air and other unfavorable conditions of city life, are now menaced by a killing epidemic are now menaced by a kning epitemic disease, the U. S. Department of Agriculture recently reported. Seven thousand of the trees are dead in the Philadelphia region, and 700 in Baltimore. The disease has also appeared in Washington.

The infestation is a slow killer. In the

first year, cankers appear in the bark of the trunk and large limbs and dark streaks in the young wood. In the second year the leaves thin out. The tree may die then, or linger one or more years longer.

The London plane is a cross between the American and European plane tree or sycamores. It is widely used as a shade tree along streets and in downtown parks because of its hardiness under cuty conditions. Its disappearance would denude many American cuty streets and leave cuty fore-ters and park commissioners at a loss to find an equally good subbitute.

good substitute. Department of Agriculture plant pathologist, is seeking information regarding the distribution of sok London plane trees. It is requested that chips of young wood from planes or sycamores suspected of having the disease be sent to the Division of Forest Pathology, U. S Department of Agriculture—Science Service.

WATERPROOF FABRIC

ZELAN is a recently announced waterrepellent finish for fabrics Developed by duPont, it is claimed that the new finish is the first which will still shed water after the merchandise has been washed or dry cleaned many times.

Other water-repellent finishes coat fibers like wax on a thread, and some of the waterproofing chemicals cover the entire cloth and close the pores of the material, making the garment hot and uncomfortable to wear

Instead of coating the fibers, it is said that 7elan goes into each individual fiber. It be comes part of the material itself without closing or clogging the pores, thus the cloth can "hreathe" and the garments are much more comfortable to wear.

AN UNFORESEEN RESULT OF AIR CONDITIONING

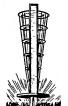

Whien an air-conditioning unit was installed in one of Boston's large pewleys stores the primary consideration was the comfort of customers and clerks. It was soon owdent that there was a more practical benefit from the installation. The himidity contion and the removal of sulfur from the air by the air-washer climinated a source of silter tarnish, and it was found that ailver articles on display had to be polished much less frequently.

THE CULTURE OF ORGANS

AT the instant of a human bring's legal Ad the hand of hours and one times even days thereafter, major sections of the body are still aliev. Consequences and many brain cells may be deed, yet at the same time the beart tissues as well as many another tissue may often be found living, merely in a low state of activity. Delt technique frequently can induce an apparently lifebase beart to throb. These facts have long been established, but little has been made of them until recently.

Now new methods yield important discoveries. The hearts of dead patients can be revived and kept beating for hours, within the body or cut out. In such revival, blood or a bloodlike symplete faul is supplied to the heart and its vessels through a double set of tubes. From one reservoir, fauld at high pressure is forced through tubes pieceing the

A FAIR WITHIN A FAIR

by Westinghouse

It has taken a World's Fair to make us realize all over again that ours is not a commonplace business. More than 12 months ago we undertook the task of erecting our own building at the New York World's Fair. Today there has sprung up a treasure house of wonders devised by the inventive minds of an organization trained to think in terms of practical applications rather than spectacular showmanship.

Instead of an ordinary cornerstone laying, we buried the Time Capsule with its significant message of our times for people who will live 5000 years from now.

In our laboratory we discovered that everyday experimental equipment could be transformed into headline attractions for a Playground of Science where visitors crowd the aisles to see the shape of their own voices, transmit music over a beam of light, and demonstrate to themselves other mysteries of science.

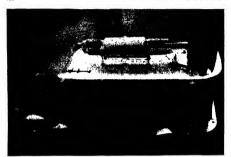

An engineer's dream was brought to fulfillment in the form of a friendly Frankenstein who walks and talks, counts on his fingers and distinguishes colors to the delight and amazement of crowds who throng his every appearance.

Our auditorium cannot accommodate the audiences who stand in line to witness the triumph of modern woman over drudgery, as accomplished by one of our lesser-known appliances.

To add to the enchantment of the Fair as a whole, as well as our own building, Westinghouse engineers took advantage of the latest developments in illumination, hydraulics and control devices to create the Singing Tower of Light with its breath-taking symphony of music, water and light.

Behind the scenes, Westinghouse has collaborated with the Fair and other exhibitors in making possible all the wonders of this World of Tomorrow. We furnished the lighting and power equipment for the spectacular Lagoon of Nations where thousands of fair-goers stand nightly in awed wonder. The longest electric stairway in the country, the exterior lighting of the Perisphere, the production of Florida climate on Long Island, are examples of a few of our transportation, lighting and air conditioning contributions to this greatest of all fairs.

It is gratifying to realize that our own people were able to take a World's Fair in their stride and handle it as they would any ordinary, everyday job. We hope you will visit our building and spend time enough with us to catch the spirit of Westinghouse which we have tried to interpret to you in our exhibits.

aorts and passing directly into the heart's private circulatory system, the coronary vessels. Frum a second reservoir which developes a lower pressure, fluid is made to flow less forcefully through another tube, that goes forcefully through another tube, that goes and the property of the sorts and the past the valves of the sorts and not her vestricle. By this method, hearts can be perfused as four hours. These are human hearts—
which had stopped all action at death. Hearts of experimental animals can be kept alive much loaser.

and noger moder to a considerable and the advent of methods which should gave the definite life to organs in glassware. They should not seen to organ should not seen to see the seen of t

WALL PAPER REMOVAL

A PRODUCT developed for use by paper hangers and decorators, Aerosol KA, decreases the tendency of water to form droplets by lowering the surface tension Thus, when one ounce of the powder is added to one gallon of water, the solution will wet old wall paper almost instantly and permit its removal more readily

SOUNDPROOF PORTABLE DIESEL GENERATING PLANT

PYERROWS went up early this apring when Paul Grosse drow his larest creation, an ultra-modern soundproof, portable, Deered electric generating plant onto the Schmick International Studio lot in Holly-wood, Grosse's striking looking "Fran child" was built from a re-vamped cab-over-engine truck chasses entirely of Durla and at a cost of \$24,000. Entirely portable, the new sound-proof generating plant makes it possible to get within 200 feet of a movie set on location without discussing the sensitive sound microphones. An ordinary generating set must be at least 1000 feet away with a need

Above: The soundproof truck, with muffler and oil radiator on the roof. Below: The truck driver's seat can be reversed so that the operator faces the convenient controls of the Diesel-powered generator

for less than one fourth the cable, transmission line losses of the high amperage direct current are greatly reduced. Grosso says he can work as close to a set as 100 feet with a building or some sort of a deflector between the generator and the micropliones.

Grosso has found a way of halancing the speed of his Diesel with the amperage loads. something electrical engineers have been trying to do for years. Any variation in the engine's speed, large or small, does not affect the voltage output which has been predetermined and set by the master control knoh This is of tremendous importance to the movie industry, especially now that Technicolor is gaining in popularity. It is well known that color movies demand a great deal more light than black and white movies Any variation in the line voltages tends to change the intensity of the artificial light which, in turn, causes the hue of the photographed color to change. As the light decreases, many colors fail to register and all tend more toward the blues.

Total thickness of the walls enclosing the plant is three inches, made in three separate "layers," with a one-inch, sound deadening, are space between each. On solid neither where sound-proofing was devired, a mixture of cork and tuther was built up with a "purp again to the proof proofing the proofing of the

SULFANILAMIDE TREATMENT OF EAR AILMENT

THE new drug, sulfandamide, has extended its sphere of usefulness to cover onte media, that extremely punful disease of the middle car that often is the forerunner of a masterial operation.

Eighty-eight patients with out is media due to heta hemolytic streptococcus were given sulfanilamide in a recent series of cases and only seven required a mastoid operation, reports Dr. Gibert E. Fisher of Baltimore in the Journal of the American Medical Asso-

In a control group of 95 patients who were given the regular treatment of puncturing the membrane for drainage and irrigation, 66 re quired a mastoid operation

Moreover, the patients treated with sulfanilamide recovered in one third the time taken by the other group—Science Service

DRY ICE AIDS WELDING OPERATION

In the construction of a 40 foot welded steel boat hull, an unisual expedient was used to prevent the high temperature from buckling the steel plates. Four cakes of dry tee were used, two made and two outside the hull. The cakes were placed as close as possible to the weld while the plates were being joined, and it is reported that the resulting flat surfaces are fully satisfactory subjusting flat surfaces are fully satisfactory.

COLORING CONCRETE

FLOORS

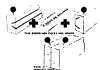

LACK of permanene and lack of revitance to measure and alkali are two bages that make two bages that make a part of the locating of converte floors after they are laid. When a panti-ype voloring is used there is superimposed a relatively soft oil fina on top of hard concrete, and this does not withstand hard triff. Also, the slikel in the concrete, in combination with moisture reacting with the acid of the vegetable oils, cause sponification, or breaking down of the paint film. Robber resum overcome this handleap to floor have been confined to the addition of a mineral color to the too.

A new system, called the Truscon Flor-Dye System, developed by the Truscon Laboratories, may be used on old and well-matured floors. The only limiting condition is that the floors must be dry at the time of application. This is called a "system" because it consists of two materials: (1) Flor-Dye, a "penetrant which stains, seals the porce, and helps hind the particles at the surface; and (2) Flor-Dye Dressing, which protects the Flor-Dye and affords a polish or sheen to the surface. In some cases, Flor-Dye may penetrate a mere \mathcal{H}_2 of an inch and in others it may penetrate as much as $^{1}_2$ inch. Because it does penetrate the concrete, the concrete still takes the way

Both materials come in four standard colors—the red, Spanish green, Julia brown, and marcon—and both materials should be used as a complete system on any floor color ang job. The system is not affected by most over a falkal in the conert to It as acid-pinosi, oil pixoli, non-staining, but not gasoline proof It cannot be applied over paint, satisfies the proof the cannot be applied over paint, satisfies, the completely removed.

SIMPLE JOINT LOCK

WHEREVER any two solul materials are joined, a new device will find auplication and in many cases will do a better job of joining. This new ilevice is the Homer Spline Lock, which those who have myesti gated it believe will find many uses in industry It supplants expensive tongue and groove connections, dowels, nails or serews dovetails, rabbetting, and lapping in wood working Eventually it may supplant also outs, bolts and cap screws for connecting parts of even the heaviest metal machinery The basic simplicity of the Homer Spline Lock may be seen in the small diagram which accompanies this item. The splines for keys) are inserted in the matched grooves of blocks A and B in an ingular relationship to each other. The result is that

Above: Two blocks are firmly jomed together by means of a simple pair of keys or splines inserted in the positions shown in the lower part of the drawing. Below How the spline lock system may be applied to a drop force or pile driver.

Waldorf Rates Have Not Increased!

THE WORLD'S MOST EXTENSIVELY
AIR-CONDITIONED HOTEL

It really doesn't cost any more to stay at the Waldorf . . . in fact, luxury and service considered, the Waldorf costs less. One of the added satisfactions of your visit to the New York World's Fair is that in choosing the Waldorf, you pay only our standard rates!

And stopping at the Waldorf is, in itself, one of the never-to-beforgotten experiences of your visit to New York.

the two blocks are bonded firmly in the desired face-to-face position. Depending upo the kind of wood used, this method yields three to ten times more strength in the joint than is obtained by ordinary means. By increasing the thickness of the metal, wood, or plastic splines, it is obvious that friction and tension are increased in direct ratio, even to the point where the two pieces A and B become immovable in relation to each other.

It may readily be seen that splines of this type, but made of steel, could be used, for example, to fasten the cylinder head of an automobile engine or the parts of a heavy pile driver. Already they are being adopted on the manufacture of window sashes, doors, and inlaid floors. In this latter use the splines lock the pieces of flooring rigidly and thus chminate the movement and squeak so often necuniered. Furniture of all kinds may be given greater rigidity with Homer Spline Locks than with any amount of bracing

APES NOT STUPID-

INST. HUMAN

MRS APE can learn by aping Mr. Ape nut because of sex difference but apparently because it is hard for a dominant ansmal to take lessons from a submissive one This observation of ape ways, of possible implication in education of their human relatives, was reported to the Southern Soctety for Philosophy and Psychology by Dr. James H. Elder, of the Yale Laboratories

of Primate Biology at Orange Park, Florida. Despite popular notions, it is quite a trick for an ape to crack open a stubborn coconut. He can roll it around and fumble with it for a long time without getting anywhere. Only once did Dr. Elder find a chimpanzee that could crack the nut by his own efforts: that seemed to be a happy accident
It takes a firm hold and a sharp pound

against the concrete floor to crack a coco-nut. After Dr. Elder had allowed his clumpanzees to struggle alone until they gave up the problem, he showed them how. Two apes learned in just one demonstration. They could then show other apes how, and they can learn just as quickly from each

But in two eases where the ape "instructor" was demonstrating for a dominating animal, the pupils could not learn even after as many as 16 demonstrations. These two poor learners were not stupid, either; one, in particular, was very intelligent .- Science Seruce.

"Z" NICKEL

OMPARABLE with oil-tempered steel in strength, stiffness, and hardness; tensile strength from 2½ to 4 times that of structural steel; resistance to wear equivalent to that of hardened steel-such are the claims made by the International Nickel Company for their recently announced "Z" nickel wire and strip.

Being 98 percent pure nickel, the metal is rustproof and highly resistant to corrosion rustproof and nightly resistant to corrosion and oxidation. It is suited for parts which must have a high order of mechanical prop-erties, together with corrosion resistant and rustproof properties. It is useful for springs

spring washers, diaphragms, wire brushes, leader wire, fish hooks, camera parts, air-plane strut wire, portable aerials for cars and boats, and other parts of electrical and mechanical equipment.

Because of higher strength and stiffness, "Z" nickel is useful for improving performance, reducing weight of parts, or both.

INCENIOUS RAZOR BLADE SHARPENER

NEW blade sharpener, with rotary honing action, hones and strops both sides of both edges of any Gillette type blade in one operation. It is a precision instrument, engineered to improve a blade edge and keep it in smooth shaving condition

Refer to the illustration. The touth shaped hones are inclined inwardly so that the grinding surfaces of the inter-engaging grind-

Just slide the case

ing treth together form a grinding angle corresponding to the cutting angle of the razor blade

With a blade in position on the pins and the case closed, the blade rests with equal spring pressure from all four inclined granding surfaces for simultaneous operation on the four sides of the cutting edge. Then, sliding the case up and down the string, the ecrentric pins cause the blade to force apart alternately the two sets of hones, producing a reciprocatory movement of the blade on the hone surfaces. Result a smooth edge for every shave New blades are improved by honing off the tiny metallic "fuzz" often left on them

The case of the Blade Master is smart and compact, being of durable Bakelite. The hones are made of a mild abrasive material with a binder, built to last indefinitely. The metal parts are cadmium plated and rust-

TRICHINELLA SPIRALIS

THERE seems to be a widespread misun-A derstanding regarding the life cycle of the trichina parasite, Trichinella spiralis. This false impression was reflected in our recent article "Animals Bring Us Diseases," in which the author wrote that those parasites ingested by the eater of pork products are the only ones to be found in the human body. The editor who handled that story unfortunately let the statement stand. We are glad, therefore, that we can give below an authoritative statement regarding the life cycle of this parasite, from the U. S. Public Health Service:

"Following the ingestion of uncooked or undercooked meat containing viable trichina larvae, the larvae are freed from the cysts by the action of the gastric juice. They then migrate from the stomach to the small intestine of the host where they develop rapidly

Experimenters - Schools - Field Workers

An Accurate Balance at a Price Within the Reach of All

Sensitive to 2/50 gram Weighs up to 100 grams Compact-No loose parts Modern, durable construction Small convenient size Handsome streamline design Now permissible for auxiliary use in drug stores (N. Y. C. Serial B17.)

Never before a balance with all these exceptional features!

I must Quality—Made of tested insterials its construction will appeal to laboratorite destring the bost equipment. The Bakette cup is unafficted by practically any substance that can come in contact with it the tool steel knife edge and agale bearing will give long life and accuracy.

treeme Sensitivity—Weight to one decima point farther than the usual tow-prices cautter avaies and serves nearly every labora-tory purpose short of precise analysis. The capacity of 100 grams is ample for the delicate

weighings made in the usual course of teach-ing, organic synthesis, experimental work, compounding, photographic work, etc Compact Convenient—Does not monopolize a laboratory table Placed on the desk of the busy technical executive, it will soon become indispensable

its small size makes it possible to carry it on inspection and testing trips at a distance from the laboratory it is small enough to be carried under the arm or in an overcoat

Graduated in either the Metric System (grame) or the Apothocary's System (grains drams and cunese) in ordering, please indicate which of these you desire

to maturity. The sexes mate within the course of a few days and the adult females begin to produce living young on or about the fifth day after infection. These young larvae very promptly enter the general eir-culation of the host and are carried by the blood stream to all, or nearly all, of the voluntary muscles of the body. Larval production by the adult female worms continues to take place for a period of approximately six weeks following the beginning of parturi-

OIL-PROOF INDUSTRIAL

WiTh the rapid development and wider uses of mechanized material handling equipment, there has been a marked increase in the use of rubber tires on trucks and trailers used in intra-plant hauling, according to Wilson C Bray, manager of The B F. Goodrich Company truck and bus tire department

"A new industrial tire, specially compounded to resist the action of animal, vegetable, and mineral oils, to be known as 'Oil-Pruf,' is now introduced," reports

Mr Bray.

"Tires of ordinary construction, when subjected to oils, disintegrate and become soft and spongy. Under such conditions, they are susceptible to rapid tread wear, cutting, and chipping Tests carried on for several years in steel mills and by meat packing companies prove that these new tires re-tain their original physical properties approximately 30 percent better than others tested when used in the presence of oils and other solutions usually classed as rubber solvents.

"The 'Oil-Pruf' tire should be a boon to companies operating industrial equipment over floors saturated with oils and greases Tests actually prove that the added service to be expected more than offsets the small additional charge necessary to cover the high cost of special materials which give the tire unusual properties," the rubber company sales official said,

SEEDLESS WATERMELONS

SEEDLESS watermelons have been produced by treating the unpollinated flowers with naphthalene acetic acid The melons were all seedless but varied in shape Some, however, were normal in shape and size The texture of these fruits was firm and solid No difference in flavor could be detected from normally pollinated fruits. The work on these fruits is being done by Cheong-yin Wong at Michigan State College

PLASTICS FUSE "WOVEN WOOD"

PANELS made with permanently finished wood veneer, fabricated by treating skilfully woven strips with plasties, are now available to furniture designers, interior decorators, architects, and others interested in a finishing material which combines dura-bility with beauty The Parkwood Corporation, in conjunction with engineers of Gen-eral Electric's Plastics Department, made the new panel material available.

The veneer is coated and impregnated with G-E Textolite resin varnishes and a remarkable toughness is the result. After cutting

the veneer into strips of the desired width, close, accurate weaving is possible. But further treatment is necessary to fuse the woven sheets into satin-surfaced, durable panels that can be cut and worked within practical application

In order to produce such panels, the woven sheets of impregnated wood veneer are cut to the desired sizes and are bonded to Textolite laminated material uniter heat and pressure The desired tough, resilient, and smooth surfaces are the result

The finished panels, in thicknesses of 3,54 or 0 020 meh, have a variety of applications Mounted on ordinary plywood or other solid

Table top of woven wood

backing, Parkwood Textolite constitutes a fine new finish for such objects as desks, card tables, cabinets, bars, walls, and ceilings Unaffected by moisture, alcohol, fingernail polish, and most common acids, the material is also resistant to eigarette burns. In the 0.020 inch thickness, it is surprisingly flexible and can be stitched, stapled, and cut with ordinary shears, like a piece of leather in either thickness it can be formed, cut, and entitled by ordinary woodworking methods

A panel of Parkwood Textolite, after the final treatment, has a surface almost as smooth as glass and a pattern that looks like a fine, highly polished mosaic Numerous effects are available through the combination. in weaving, of various light and dark woods Panels are ordinarily made with light or dark red mahogany, avodire, a golden-shaded wood imported from the Ivory Coast of Africa, birch, either red or white, New England maple, and walnut

BACTERIA IN WATER MAINS

T has been found that bacteria multiply in hemp. For this reason a rubber compound made in tubular or wedge-shaped sections is replacing jute and hemp as caulking materials for water mains Tests have shown that sterilization of hemp and jute can be accomplished, but bacterial multiplication starts again as soon as the germicidal action ceases.

NEW LIGHTWEIGHT INSULATION

NEW product named Celotex Superlite A Insulation, which should be of special interest to the refrigeration field, has just been announced. It weighs less than 71/2 pounds per cubic foot but high insulation and sound absorption values are claimed for st. It is of board form, but is a soft, nonstructural insulation. It may be fabricated, cut, or bent to moderate curvatures to fit

INDUSTRIAL SLIDE RULE

THE Langener Industrial Slide Rule, man-THE Langener Industrial Since Source, pany, is designed to solve an unusual range of industrial problems, yet in a simple way, with only one movement or setting of the slide in the majority of cases.

The Langsner Rule was developed to the practical requirements of mechanical engincers, industrial engineers, shop men, time atudy experts, and machine designers It is simple to read even for the person who is not a slide-rule expert It is 10 miches long,

	dh	40.015		-	***		***		-
	Acres 6	5	-	-		1		- 2	
		in a contract of	Ja.			٠,		÷

methor	and sale	Acres 6	Lon Inc	artes.	mer	in A line	or Asset		

engine-divided on white celluloid, with glass-"frameless" indicator, and is packed in a case with book of instructions.

The Langener combines many rules in one although there is only one slide. The face has six scales. Two of them above the slide represent feed, length of cut, and diameter, three of them on the slide represent revolutions per minute, time, and cutting speed, the regular D scale is below the slide. The reverse side of the slide contains the usual B, CI and C scales, for standard slide-rule calculations Three of the face scales are numbered in red, the remaining three in black, for convenience in use. The table on the back presents familiar constants

With the new slide rule, solutions to many problems are obtained at a glance, such as surface speeds, cutting speeds, diameters of cutters, drills, and so on, required revolutions per minute of any work; feed ratios, length of cut, time required, time-study data, and other factors

NICKEL FROM CHLORIDE

SOLUTION

O replace the conventional sulfate elec-To replace the conventions, a process has been developed employing a nickelchloride-boric acid solution. The new chloride bath is said to produce a deposit which is finer grained, smoother, harder, stronger, and somewhat less ductile than ordinary nickel-plating deposits.

In addition to the above advantages, a 50 percent reduction in tank voltage and wer consumption is permissible; control of the bath is easier; and high anode and cathode efficiencies are attained. The plating is more readily buffed, has less susceptibility to pitting, and has less tendency to form nodular growths and trees on thick deposits.

STREAMLINED TURKEYS

THE sim of certain turkey-breeding work is to develop a small turkey to fit the modern small oven and suitable for the modern small family, according to Berley Winton, in charge of the Department of Agriculture's poultry-husbandry investigations. There is a

Industry Accepts SCIENTIFIC AMERICAN

-THE ONLY National Publication to show a consistent FIVE-YEAR GAIN in Advertising Lingge, 20% GAIN IN 1939 OVER 1938!

Dependence follows quickly upon acceptance and Scientific American, because of its exhaustive treatment of industrial research, has won the acceptance of leaders of American industry.

Not content with merely reporting the news of the frontiers of research and invention, Scientific American long ago began showing industrial leaders how to apply the new developments from those frontiers to today's procedure.

And in today's procedure, Scientific American plays a definite part. Industry depends upon this publication to bring it the guiding facts that lead to the purchase of the products advertised in Scientific American pages.

Build your sales upon this dependence. Know that your selling facts are read by the men who do the buying, in the publication that impels their buying interest.

Ask us to show you copies of the letters received from American industrial leaders seeking buying guidance from Scientific American.

Send for our complete illustrated list SELLRIGHT GIFTWARES CORP. 836 Gates Avenue Breeklya, N. Y. growing demand for small market turkeys, he says. The smaller turkeys out of the annual crops of the standard varieties sell at a premium of ½ to five cents a pound.

It will take probably another five years before the desired characteristics are "fixed" in the new small-type turkey. Winton points out For that reason, the Department will distribute no breeding stock, batching eggs. or poults until the geneticists are satisfied that the small type turkey is "genetically pure" for small size and other desirable qualities, and able to reproduce itself true to type, in the future

The Department geneticists want to establish in the new turkey the small size of the white Austrian variety imported from Scotland and of strains of wild turkeys from \nginia, Pennsylvania, Michigan, and Arizona They hope the new turkey will also inherit the meaty breast of the wild turkey

To reinforce the inheritance for white olor, the geneticists are using the white Holland in the hreeding program to produce the small-type turkey. They are also counting on the white Holland-and two other domestic varieties, the bronze and the black to contribute early maturity and other desirable characteristics

If the Department men succeed, the smalltype turkey will be white, with a compact hody, short legs, a long keel bone, and plenty of breast meat. It would mature in 24 to 26 weeks, the young hers weighing 61/2 to 9 pounds dressed, and the young tons between 11 and 151/2 pounds dressed.

Other goals for the new turkey are that hens kept for lireeding purposes be able to produce a reasonably large number of eggs by June 1 Ninciy percent or more of the eggs would be fertile and 80 percent or more of the fertile eggs would hatch

INSULATION OF GLASS FLUX AND MICA DUST

I N the German electrical industry, a new insulation material, now in use, is composed of a combination of glass flux and mica dust. It has the advantage of being extraordinarily firm, maintaining a high heat content and a minimum of dielectric current loss. This material is important in high-frequency technique and in the manufacture of electric switches

COSMETIC TO PROTECT WORKING HANDS

NUMBER of skin protective creams A NUMBER of skin protective creams— sometimes called liquid gloves—have heen on the market for years. These have been used to protect the hands of working-nien against the action of various kinds of chemicals, paints, and solvents.

A new compound for this purpose, called "Shelltex," is made of such pure ingredients that the manufacturers claim that it is even safe to eat. In using this, the workman first washes his hands thoroughly and dries them, after which he applies a liberal quantity of Shelltex and rubs it in until the sticky feeling disappears. This one application shields the skin from dirt, gasoline, paints, inks, lacquer and lacquer thinners, and most sol-vents. The flexible film on the hands does not interfere with work and 18 easily removed by washing with warm water and

MASTERY OF LIFE!

There is no man more independent in life than the one who KNOWS that he know. He is master of every situation and the conqueror of every problem. He takes possession of the opportunities over which others ponder in doubt. There is nothing that gives one that courage and determination which make free course; if the life was the courage and determination which make er success in life, like the knowledge for success in inte, like the knowledge of knowing what to do and when to do it. Think of being forearmed with a wealth of wisdom that makes it possible to choose wisely and rightly and to avoid mistakes! Could there be any greater treasure in life than this?

PHOTOGENIC NEW YORK WORLD'S FAIR

THEX just couldn't usstret the anatem. The New York World's Fair was too full of good picture material to say to plot outputs with the material to good picture material to say to plot outputs with the same of t

But the best stuff is conflower, and that is all to the good because there is molting to be at sandpilt for general shooting. There is one hazard in this connection lowever, and that is the fact of dependence on the squaies of the washer? Under a model to and grace to shorts of the Fan buddings. In he of clouds for three seem always to be absent on just the day you happen to visit he Fara, a courtes; thirt with a the orange will go a long way by providing a dark tone the Bard and the stuff of the seem of pertines to the blank sky, thus avoiding the white paper effect that is the larne of pertines filter was used in making the whot of the principal illustration for this article. The exceent shadow of the Typlon case across the Sphere invited photographic attention but was not until the viewpoint shown was rached that an interesting composition presented used. Clouds seemed imperative, but the orange filter supplied a good substitute, in fact, a substitut that was very appropriate to the scene.

The Theme Center, consisting of the Persphere and Trylon, may be seen from most sections of the Fair grounds in majestic

"Archery at the Fair"

"Pageant of Stone"

reign over all the activities within the was area. Doublews the majority of pretures taken of the Far ruther noticule the Theme Center within the view or make it the sole subject of the perture. One might easily some feature of the Far with a view, near make up a whole series of short ying say some feature of the Far with a view, near or runte, of the Thirm Center, Small stops will often be necessary, as in the case of "The Timer Center, Small stops will often be necessary, as in the case of "The Timer Center Percudes All," but small stops are easy at the Far, where the presence of so many light-toned bouldings under a wast sky makes small stops or very short reposition.

use the new fast films in order to take care of indoor situations and the possibilities to come at night

Frequently one rons across isolated bits of scolptine such as that of the winged subject illustrated here. This was taken against the son, with the latter positioned directly behind the base support of the subject "Archery at the Fair" os an example of the

"Archery at the Fair" is an example of the sort of picture that will require several shots in order to make a later selection of the most interesting arrangement. In this particular case, the three most attractive figires in the line up were chosen as the main point of foots.

point of fector.

Night showting at the Fair is cessly accomplished with the fast films and fast lenses, Most shows will be in black and white, but you will be missing the "opportunity of a letterine" foy due not attempt some color. Exposures are relatively long but the binds and the state of 128, white other shipers, such as the color display in the fountains, will call for exposures at this stop ranging from 1/5 or * \$45 to 1/25\$. Cheen or similar camera supports are in order For many cameramen the World's Fair is most attractive at night cheefly because of the color highly angle.

Needless to say, a good film supply is the best insurance against running short just when you're getting into the awing of the thing. If you plan to carry an extre camera for color, plus accessories, one of the popular combination "catch-all" zipper bags will be found handy.

Uses for Blue and U.V. FILTERS

ALTHOUGH little publicized as compared with the yellow, red, and green filters, the U.V. and blue filters are found useful as several different ways. The U.V., for example, is employed to cut out haze when it

"The Theme Center Pervades All"

is not possible to employ other filters, for the purpose because of the longer cynosire required For example, if the lons is stopped door accorded rayly and the meter was to give 1.25 of a second, it would not be possible to use a filter unless a tripod were available for the yillow or red filter would call for a with the camera bed in the hand. The UV, filter omes in handy in such cases because it does not exput, any increase in exposure.

The blue filter band us greatest overfulness in indoor photography. When subjects has ung a fair skin are photographed by artificial high on panchromatic thin, the resilts do not always show pleasing field tones. We have found that the new of the blue filter placed over the lens greatly uniproves the results Annohra we for the blin filter is in the projection of two by two-and to older slides. We have processes we calculate find that the same processes we calculate find that the Shipping a blue filter over the bras has resulted in uniprovement of the color values.

How Cartoon Movies Are Made

DESIGN AGAINST THE SKY

THE extreme usefulness of the reflex camera under particular circumstances was demonstrated the other day when, strolling in the park, we gazed upward and saw outlined against the sky the beautifully curv-

"Design Against the Sky"

ing branches reproduced here. The peculiar formation was directly overhead, and, with the reflex camera we happened to be carry-

ing, it was a simple matter merely to hold the camera so that the lens was pointing directly upward, while we observed and composed the subject at eye-level position without straining the neck

SHOOTING AFTER A

DAMP NIGHT

AMATEURS containes complain of undataproses appearing un one picture while the very next exposure seems to be perfectly satisfactory. Thus may be due to any one of a number of causes but one of the reasons not ordinarily realized is that when a loaded camera has been exposed to a night of dampees or ran, the film is inclined to warp a little, causing unevenness of surface The renedy is to wate one shot and thus get rid of the first film frame, going at the third of the first film frame, going to the third the film frame, and the follow ut with another just to see what the results are.

THE DIVING CYCLIST

AT a stated hour, announced long in advance, cream "axis of daring" and so forth are performed in the anuscement parks. The picture of the diving overlist was made at Rys Beach's Playland. A position was assumed that would include some of the spectators, and a small enough stop was used —//11 being found sufficient—to show in satisfactory sharpness both the rapidly moring whiject and the spectators near this

submitted must depict the thenic of balance in some way For example, a photograph of a boy balancing himself on a narrow fence. a newhorn hahy being weighed in a scale, or the balance of a sailboat turning gracefully in the wind. Cash prizes will be awarded

The sponsors say "The halance idea offermany suggestions to the photographer During the summer season, the traveling circus and the county fairs offer many opportunitus for getting pictures illustrating balance. The acrobats, jugglers, and barehack riders all lead themselves to pictures eligible for entry in the contest ' Closing date for the contest is November 1, 1939,

By Proxy for the Sun

A STRONG reflector of light will behave in practically the same manner as the light source itself. For example, we are all familiar with the path of light cast by the sun across a body of water. In the picture reproduced here, taken from a feeryboat a-

Light reflected from windows of one of the tall buildings in the background was strong enough to produce this "sun path" effect

it approached downtown New York City late one afternoon, the windows of the tall hilldings all reflect the sunlight, but in one or two places, this effect was particularly strong In those places the result was a glare, and the long "beam" cast upon the water is very similar to that which the sun itself

PROOF OF THE PURDING

WHEN it's your "yes" against the other man's "no," let the picture decide the issue At least that is the way one deter-mined chap booked at it Recently, a camera owner who had found that the foot scale on he outfit did not check with the ground glass, came with his complaint to the camera emporter There the repair man told him that he had checked the camera and found it to be O.K. The customer had his doubts He set up his camera on a tripod and used for subjects a number of books set on end. the tacket cover side facing the camera. The books were carefully spaced, with a ruler. six inches apart, and the distance from each volume to the camera also similarly measured. A photograph of the set-up showed that whereas the scale read five feet, the book

"Make Money With Your Camera"

Photo-Markets

This 144-page book tells what to "shoot," how and where. Gives directions for submitting photographs to magazines. Lists hundreds of markets for photographs, together with the types most suitable for each.

SCIENTIFIC AMERICAN 24 West 40th Street New York City

Profitable Photography with the

Miniature Camera By Edwin C. Buxbaum, A.R.P.S.

BESIDES having a considerable amount of fun with the miniature camera, making trick "shots, art photographs, and the like, you can also use it for special paying work. This little paper-bound booklet of 72 pages tells not only how to make interesting photographs that are salable to news agencies or magazines but also gives many clues to the very large number of types of photographs that can be sold. For those who wish to mix profit with pleasure this booklet should prove most helpful.-\$1 10 postpaid.

at this distance was out of focus, although the book at six feet was in perfectly sharp focus. When he brought in this "evidence" he did not have to say a word. The picture told the story.

PIGEONS AT REST

In the city pigeons are everywhere, most appropriately in the public parks. With the squittels and the ducks, they are continually being fed, and often photographed Frequently they may be seen lined up in a row, as in the illustration. An angle shot,

"Pigeons at Rest"

with the lamp offering an agreeable accent, and the few leaves in the upper left concer-"filling in" for balance, brought the subject into a reasonable composition. Too, the pigeons are neely spaced so that the interes is spread across the entire length of the diagonally placed lamp-post xtension.

HANDY RECORD BOOK

BEFERN(Es to formulas, methods, and other photographic data are made easily as cessible suit the Rech-Record, a visible and made system available in poket sor the individual cards measure 2½ by 3 inch es a quarter inho edge of each being left uncovered for the index The card, while trainers until affords seningly room of a formula or process, as well as flash exposite data, and so on The book may be carried about in the pocket and whenever int runs across a new formula or other information that may prove useful later either in shoot in printers of advisions work, the record can be made immediately. At work such a morleads can moreluse from vanishilate morleads can be made immediately.

BETTER GET STARTED!

CONTEST thoing dates have a way of the covering store that the covering store to the old expression: "Where has the time gone to "In the case of the Fourth Annual Scientific American Photographus Contrest, the choung date was purposely placed far enought in advance to enable every not to make adequate prefarations for submitting their per prints. But therein her possible source of difficulty. With the change possible source of difficulty with the change that the change is the chance that some amateurs are going to think that there is so much time for preparations that they will put things off until the last minute and heuce fail to reag the in

F R Exposure Meter (\$1) Extinction type photographic exposure meter. May be set for any film and for any light condition. Use ful for both still and movie cameras, readings showing both regular still aperture num bers and shutter speeds plus movie frames per second. May also be used to determine exposure with various filters, without cal culation or guess

UNIVEX CISE TELEPHOTO LESS / 35, 1 inch (\$10.95) · In micrometer focusing mount For use on Univex Cine cameras Gives twotimes magnification, making it suitable for sports, portrasture, and so on

Merci by Rapid Winder (\$250) Accessory for Mercury camera converting it into unit for rapid sequence shots Permits shut

ter to be set and film transported without iemoving camera from eye, making possible a dozen shots in few seconds Winder is attached

by unscrewing shutting winding knob, replacing it with special geared knob and screwing bracket into cable release socket on top of camera. Entire unit detachable in less than one minute

SKINNER RESTITUTIONAL ENLARGER FORtures negative adjusting device enabling operator to tilt negative from horizontal plane, optical system always remaining in perfect alignment, double condensers, takes negatives from 21/4 by 31/4 inches down to 35mm.

NLW STANDARD 6 by 6cm ROLLEIFLEX (\$128.50): Taking lens is Zeiss Tesas //3.5; finder lens, f.3.1. Cumpur shutter speeds to 1/500. Shutter speeds and disphragm openings visible from above, through one window, adjustments being made with two levers, one on each side. Automatic film transport after locating No. 1 in red window.

BOOKS

r Amateur Photographers

New Ways in Photography, by Jacob Deschin. Eminently practical from every point of view, this new hook contains nothing of theory and nothing that the advanced amateur photographer will not find valuable in one way or another. It covers the in one way or another. It covers the whole range of amateur photography, discussing surh things as trick pho-tography, photomurals, retouching, infra-red, and a number of other sub-divisions that will not be found elsewhere in as clear and concise a man ner, \$2.85.

SO YOU WANT TO TAKE BETTER PICTURES, by A. P. Peck. A friendly, factorine chair with the camera owner who has his developing and printing done at the photo shops, yet wants to know enough about his comera and its uses to enable him intelligently to utilize it to best advantage. Over 200 pages, dozen of illustration. \$2 10.

UNIVERSAL PHOTO ALMANACAND MAR-LET GUIDE. How, when and what to photograph in order tu make muney with your camera; where to sell dif-ferent types of prints. \$1.00.

AMATEUR FILM MAKING, by George H Sewell, A.R.P.S. Useful to the begin-ner as well as the expert morre maker. Tells about films, cameras, exposure, film editing, story telling with the camera, and so on, Illustrated, \$1 00.

CHAMPLIN ON FINE GRAIN, by Hurry Champlin, A consplete hand-hook on the entire subject of fine grain, in-cluding formulas and how to com-pound and use them. \$1.85.

PHOTOGRAPHIC HINTS AND GAUGEIS, by Fraprie and Jordan. How to moke all kinds of photographic accessories; from film clips to cameras to lighting equipment, and so on; 250 articles and neorly 500 illustrations, 33.60.

POSTRAIT PHOTOGRAPHY, by H. Wil-liams. Fundamental principles of composition and lighting, paving the way to satisfactory results in this particular branch of photography, 81.35.

PHOTOGRAPHIC ENLARGING, b/ Frank-PHOTOGRAPHIC ENLARGING, b), Frank-lin I, Jordan, F. R. P. S., One of the most interesting and authentic books on enlarsing. Its 224 pages cover every phase of the subject and 75 illustrotions, many of them adon-sinuers, shout the value of correct technique, \$3.60.

SCIENTIFIC AMERICAN

24 West 40th Street New York City

BOOKS BOOKS Double exposure avoided because crank will not turn until abuter has been released and shuter cannot operate again after making an exposure until crank has been turned. Shuter fully enclosed. Camera provided with folding mrare (conceased in finder bood), permitting eye-level focusing and compoing. Camera includes leather carrying case: Camera introduced to fill gap between Model II Rollecord and Automatic Rollelfer.

ELECTRICAMERA (\$8.75): Is a complete box camera with an electrically operated shut ter synchronized with an Abbey Flashgun Because of the basic-

ally new principle involved in synchronization it is practically impossible to miss the peak of the flashbulb. Any flashhulb may be used, regardless of timing characteristics, because the electrical

shitter automatically catches the peak Electricamera allows for side lighting, remote control, and other features associated with more expensive equipment

VICTOR ADD-A-UNIT ANIMATOPHONE: 16mm motion picture and sound apparatus permitting adding additional units as desired Starting with small basic sound projector, complete in itself, outfit of any size can be secured by adding auxiliary units. Basic projector provides silent or sound motion picture, microphone facilities, and phonograph record amplification for average size room. Adding amplifier and another larger size speaker furnishes ample sound motion picture or public address facilities for large auditorium Broadcasts, recordings, and announcements may be relayed to as many rooms as desired when Central Radio P. A. Sound System unit is added.

Zeiss Tenax I (\$60): Makes 50 pictures one by one inch on 35mm Contax daylight loading spools Features a lever that winds

both film and shutter, Exposures possible at rate of one per second for sequence picture-making. Equipped with Novar 1/35, 3.5cm focal length lens.

field afforded by this lens, when focused at 8 feet and stopped down to //16, depth of 8 feet and stopped down to //16, depth of 6 feet detends from four feet to infinity. Comput shutter from 1 second to 1/300, and bulb. Fitted with large eye-level optical view finder. Rewind device provided for other than contact spools. Exposures automatically counted. Lock prevents deable exposures. On the contact spools of the counted for
MELLOWBLAM LIGHT DIFFUSERS (\$1.75 to \$6): Features new "light-carrying" material Lucite. Can be supplied for all models of Victor Lighting Units. Use of Lucite in combination with, Fibroglas held to be of particular value when used in color photogramy with the combination with the color of
not change color of light source. Claim is made that these diffusers provide good light distribution properly diffused, retaining its original characteristics under prolonged use without distinguistic of discoloring from heat or age. Exposure time recommended is twee that of undiffused light.

X-ACTO AUTOMATIC MAT CUTTER (three sizes, \$6.50, \$10.50, \$15). Precision instrument for hevelling, enting, sooring, embossing, trimming In cutting picture mats, pre-marking is eliminated. Device features "Mechanical Wrist," made of solid bronze and slotted at angles of 55 or 90 degrees. All metal construction.

ALA MINIPAN. New film for documentary recording. High revolving power. Speed, contrast, color sensitivity, anti-shalation in proper balance. Capable of recolving up to 135 lines per mm. 15400 lines per inch.) varying with precisis not fercoding equipment used. Available in following units: 100 and 200 foot rolls, 200 foot rolls, 200 for rolls, 200 f

Solar Copying Stand (\$24.50) For use in copy work, table-topping, macrophotography, and so on Provides platform for mount-

ing subject in perfect focal plane with camera. Camera support affords universal adjustment of camera position, both vertically and horizontally. Camera supporting arm fully counterbalanced. Movement up or down the post controlled by over-

size wheel knobs operating friction claims to lock all units in any desired position Vertical adjustment to 36 inches from baseburn!

KINGSLEY SQUEFGER PLATE CLEANER (6-oz. hottle, 30c). For all ferrotype plates—chrome or japanned

WILLD FAVORITE EAUL. (\$9.75): Allement combination seal and paper obmet. Easel forms cover of light-tight cabinet. Margina controlled by drawing out lever. White surface facultates focusing and image arrangement on easel. Enlargements up to 11 by 14 inches directly on easel Cabinet permits storage of paper up to 14 by 17 inches. Ribbed visibles padding on bostom of cabinet activation of the cabinet padding of bostom of cabinet cabinets accidental skidding during calletgms.

D. JUR-ANSCO PRECISION SUPERIMPOSITION IMAGE RANCE FRINDER (\$5.50): A merican made, incorporating large, sharp-focusing method. Extending viewing eyepiece for rapid centering and reading of image. Focusing of least finder by micrometer ball-bearing dajuster revolving in bronase bearing. Uniform dial markings. Moving parts of steel, May be fitted to say camers. Internal construction allows for large light area. Complete with sling and leather carrying case.

◆ Perfect enlargements—that's a goal more easily reached when you use a Wollensk Enlarging Volontimat* For this superior enlarging lens fistifically respectives. All that you estable no your regarders Free trail period Speeds (3.5, 14.5, 16.3, focal lengths 2" up, and inexpensive, loo!

ABBEY PHOTO CORP.

JACOB DESCHIN, conductor of our "Camera Angles" department, while masser in these columns, questions of period interest to amotive programmers. If an answer is desired for mail, incluse a stampel, addressed or draw comparisons between manufactured products nor to advise on the purchase of equipment or materials—The Edition.

Q. We are obtaining equipment to take pictures in color of pathological specimens such as livers, hearts, lungs, and so on, of poultry for the purpose of projecting same on screen. All work will be done by Photoflood illumination because of the constancy of the light source, Reflected light from the object will be measured by an exposure meter at 12 inches. Questions: 1. Should the object he illuminated by one Photo flood lamp directly over the center or two lamps so placed as to illuminate from the sides? Since the specimens are moist, there will be streaks or spots of intense light on them. How can these be climinated? 2. What general or specific rules would you suggest in respect to the color and type of back-ground, and what kind of material would be suggested for the background? 3. The writer has been advised that the smallest opening or higher "f" value gives the greatest detail in the picture. Is this the general rule and may the smallest opening be used? What difference would there be in the resulting picture between an object strongly illuminated at short exposure or moderately illuminated at a correspondingly longer exposure? 4. What "tricks of the trade" are recommended for obtaining third dimensional effects? 5. On the table of film speeds we have, two values are given, one for sunlight and one for tungsten. In which classification would Photoflood and Photoflash fall? 6. Is Photoflood illumination satisfactory for Kodachronie film in bringing out good color copy?-S. A. R.

A First, we must question your use of the word "constanty" in describing Photoflood light The intensity varies with use, growing weaker from one time to the next The measuring distance will depend on the size of the arcs being photographed Centrally speaking, the measuring distance should be roughly equal to the width of the subjuct, that is, if the subjuct necessares say by eight that is, if the subjuct necessares say by eight the subjuct in the subjuct necessary and the subjuct n

sources should do the trick of entting down the effect of strong light on moist specimens 2 Use a background of medium gray or somewhat lighter tone. The purpose of a background is to afford an area of contrasting tone to that of the subject being photographed so that the latter will stand out clearly. The material used is of no consequence It may be cardboard or felt cloth, the latter is most widely used by photographers 3 The greatest sharpness of a lens is generally about two stops smaller than full aperture but greater depth of field and more details in sharp focus are obtained by stopping down the lens consulcrably, even to the smallest opening. For subjects such as yours and particularly since you are photographing in color, where sharp detail is important, the smallest opening is to be advise I Strong illumination as compared with mod erate illumination is not entirely a matter of exposure, better tonal quality and diffusion of light into the shadows will be had with moderate lighting-and usually the reverse with strong lighting 4. The best "trick of the trade" we can think of is to use a stereo camera Short of that, we might suggest "playing" around with the lights, making one a little weaker, or moving it farther away, than the other. 5 Photoflood lighting comes under the tungsten heading Photoflash cannot be measured, exposure being governed chiefly by a table of distances available from your dealer or the manufacturer of the flash lamps you are using 6 Photoflood lighting is the most widely used type employed in color photography.

Q. Does an cutomatic film transport permit a camera to take sequence shots? If not, what does determine if a camera will take sequence shots? After all the film is exposed, isn't it best to develop it right away? A friend sava it does not matter if it is developed event when the control take. Who is corcert? What other kinds of range finders are there. J. N. B.

A It is not increly the automatic film transport that permits a camera to take the rapid sequence type of pictures you evidently have in mind, but the fact that shutter wind and film transport can be accomplished with innusual rapidity. Sequence pictures can be made with any camera having the couvenience of automate film transport combined with abutter ward, the number of abots within a given period depending on the type of abutter wind and the abulty of the photographer to work the controls rapidly Special sequence cameras are available on the market group givetures on enth square and 50 to the roll. Streetly speaking, these are the only time sortled sequence cameras, which were the speaking of two miniature cameras, which were the speaking the speaking these speaking the speaking

It will do no harm to delay development of a roll of film for a reasonable time, say a mouth or so

The coincidence type of range finder, in which two overlapping images appear, sharp focus being achieved when the two are superimposed or coincide, is the other principal type.

- Q. Can you give me a rough idea of how many four by five-inch prints can be developed in 16 ounces of metolhydrochinon developer before it has to be disearded?—C. W. G.
- A Under favorable conditions that is, inhampered by such luzards a secedental transfer of hypo In the finger tips, and so forth—about 75 prints of the size you mention can be developed without clonge in developing time or print quality, using 16 ounces of MO developer.
- Q. Enclosed is a negative showing the reflection of a lighted electric sign projected onto the sky in a night view of a city laudscape. Can you tell me the cause of this reflection and how it can be remedied in the final print?— 1.1.K.
- A The reflection you refer to is exactly the same as that idealined when shooting thereily into a light source. Internal reflection between the lens surfaces is the cause fitted thouse of the reflection, it will be an easy matter to spot it out if furnited on non-slower paners.
- Q. I am going to purchase a folding type camera with f 4.5 lens that takes pletures 2½ by 3½. May I have your opinion on the quality of the lens and shutter equipment of the cameras I am listing? How do the three lenses and shutters compare?—C. V.

A State we are not in a position to a state of a camera up against another, it is not one camera up against another, it is not possessed to a recommendation from the standard not be conditioned to choose return a standard not be conditioned to the contract of the standard not be conditioned to the contract of the standard not a spanned to a top-speed of 1.250 of a second as against 1/170 non use of the other camera. As for the lenses, you should be able to make good pottures with any one of them All other things being equal, the deciding factor will be an individual ones how do the cameras appeal in you from the point of view of conviences and pleasure in handling?

Q. My... camera stops and speeds do not correspond with those on my ... exposure metter. Can you advise me how to use this meter scale with my camera?—C. G.

A. It is generally more advisable in photography to give the longer exposure rather than the shorter one. We would suggest, therefore, that since the meter does not indicate a

speed of 1/75 of a second, you either use your 1/50 speed and ignore the 1/75 or adjust your disphragm indicator between stops, should you want to use the latter speed Similarly for the 1/200 speed, which does not appear on the meter scale As for the stops, the scale stop f/28 can be used for both f/25 and f/3 on your camera; the scale stop f/4 for f/55 and f/55, and the scale stop f/6 for f/55 or for 1/55 or for lowing stops to nymir camera f/9, f/125 and 1/18, respective.

Q. In order to obtain dark sky effects I wish to buy either an orange or a red filter. Will you please advise me which is the better one to buy?—I., K. M.

A Sometime go the red filter was usually recommended to this purpose, but more recently the orange filter has taken its place in the popular factor One of the resons is that the orange filter has a lower exposure factor than the orange filter has a lower exposure factor than the red; in fact, it is usually about half, the red requiring about eight must be normal exposure, the orange only four Another reson is that the red filter decision of the red filter of the red filter or
Q. When I wish to cut off part of a 35mm roll in my camera in order to develop a strip of film before the entire roll has been finished, how many frames must I lose in reloading the unused portion?—D. A.

A We estimate that in reloading the imused portion of the roll of film after cutting, you will necessarily lose about three or four frames

It does sometimes happen that a few printare desired in a lintry. Many photographers, however, buy bulk film and had their own riels with lengths of film which will be economical and convenient for the subjects to be shot.

Q. Can you explain the meaning of the term "genre" when used in describing a type of picture?—A. F.

A This term refers to a picture that tells a story For example, two children at play, a laborer at work, the portrait of a woman knitting or engaged in some kitchen chore, are typital gentre pictures. In short, any picture that shows a person engaged in doing something is properly classified as of the genre type.

Q. I am enclosing some prints and films; the prints have dark spots caused by corresponding light apots in the films. I have my developing done by a local concert and these spots seem to occur at random on different rolls. Some have suggested the spots were caused by error in developing and some hy dirt or dust on the lens.—B. V. C.

A. As examination of the organizes does that the hals spots to which your refer are undoubtedly caused by incomplete develop ment at those points. This may have been due to negatives stecking together at the particular point and preventing full development or development blocked locally by some other unterference. The fact that the image is almost fully revealed at these points by the properties of the properties of the pointcular point in question prevented a density comparable with the res of the negative.

Here is the latest streamlined delilion to the popular the of Bodling 5, time miliatures it is remarkably light and compact vet e. a previous instrument, in evens sense of the word Among list annu features it a built in range index—tenses in ironized and outcits) perfect—operating on the spill—lange principle All control ports are easily located and quilt's winparent for taking britters in topid verversion. TELESCOPTICS

A Monthly Department for the Amateur Telescope Maker Conducted by ALBERT G. INGALLS

ENTIRE space in this month's department is given to an informative article on "Some Applications of the Schmidt Principle in Optical Design," by D O Hendrix and William H. Christic, of the Mount Wilson Observatory of the Carnegic Institution of Washington The former is Assistant Optician in the Mount Wilson Observatory Optical Shop and Oppician for the Foundstion for Astrophysical Research The latter is an astronomer on the Observatory Staff, specializing in stellar spectroscopy and com-

Figure 1. Bernhard Schmidt's first Schmidt camera photo, now historic

puting He also takes active interest in instrument design. The following is the article by Hendrix and Christic

O'E of the most outstanding inventions in optics of modern times is to be eredited to Bernhard Schmidt, late optician of the Hamburg Observatory in Bergedorf.
The first Schmidt camera saw the light of day one sultry afternoon in the late summer of 1930 Using the camera as a telescope, Schmidt and a friend amused themselves that afternoon by reading the epitaphs on the tombstones of a nearby cemetery, and by looking at various buildings in the distance Among other objects was a windmill about two kilometers away, in Figure 1 the reader will see the reproduction of a photograph of this windmill, made by Schmidt with the first Schmidt camera. This photograph was made on a moonless night with an exposure of two hours. On the original print one can actually count the twigs on some of the distant trees

As in most great inventions, Schmidt's method of eliminating come and aberrations from reflecting telescopes is simplicity itself and, as one looks back, it seems incredible that no one appears to have thought of this smple solution long ago Several articles have been written about

the Schmidt camera since the inventor set forth its principles in 1931, but little that is new has been included in these discussions. Since there are many ramifications of the schmidt principle it has seemed worth while to discuss this remarkable camera and its applications fairly completely, for it will be found that there are but few fields in optics where this invention cannot be applied to some advantage

The outstanding defects in the images formed by lenses and mirrors are spherical aberration, coma, astigmatism, curvature of the field, distortion, and for lenses we have, in addition, chromatism. Of these defects, only one is distributed uniformly over the whole field, this defect is spherical aberration. all other defects are proportional to their distances from the axis

Now a spherical porter has no axis and furthermore, a mirror is perfectly as bromatic so, could we but find a method of eliminat ing spherical aberration from the images produced by a spherical concave mirror such a

system should prove ideal

Spherical aberration is caused by rays from various zones failing to come to the same focus, the more distant the zone is from the central ray the closer its focal plane is to the mirror This defect, for spherical concave mirrors is shown diagrammatically in Figure 2, at A Suppose now, we place a very small aperture in a sereen at the center of curvature of a spherical concave nurror, as shown at B. this aperture will limit the size of the mordent beam so that the center and outer zones will come practically to the same focus for it can be hown that, for small apertures, and focal ratios less than / 10, the Rayleigh limit of λ/1 is not exceeded. If the incident beam be swing about the point o, all parts of the mirror will be illuminated in turn and the focus will trace out the spherical curve, fl. which has its center at o It will be seen that each point source of light toward which such an optical arrangement might be turned

On increasing the size of the aperture the focus is no longer sharp spherical aberration is now appreciable, but we can eliminate this defect by introducing equal and opposite aberrations into the incident heam as shown in C These opposite correcting spherical aberrations may be produced by a suitably shaped lens, or mirror, placed anywhere in the parallel beam for one particular point ree of light, but when we are dealing with more than one source it becomes im perative to place the correcting plate in a position common to all rays, that is, with the optical center at the center of curvature of the mirror. For many purposes a large field is not required and it become more convement to move the correcting plate away from this position and perhaps incorporate it with some other optical surface, such, for example, as the face of a prisin or the collimater of a spectrograph. The corrections, of course, are not identical for all positions of

On introducing the correcting plate into the incident beam of light we also introduce chromatic aherrations For moderate apertures this defect is negligible, but when we attempt to make a camera with an aperture greater than its focal length we run into difficulties; how these may be partially surmounted will be discussed later, Of course it is possible to design an achromatic correcting plate by using two plates of different indices of refraction. It is also

the correcting plate

possible—and practical—to distribute the required corrections between several surfaces when it is desirable to avoid deep or steep curvatures

The curvature of the field may be removed (approximately) by means of a simple plano-convex lens placed immediately in pie piano-convex tens piaced immediately in front of, or in contact with, the photographic plate, the plane side facing the emulsion. The radius of this lens is f/3 for glass with an index of refraction of 1.50. This is satisfactory for cameras having an / ratio of / 5 or less

Applications of the Schmidt Princi ple: In the accompanying diagrams, Figure i, we have portrayed some of the numerous adaptations which may be made of the Schmidt principle Unfortunately, Schmidt left no account of the various ramifications of his camera of which he must have thought, and we do not know, in most cases, who originated the various arrangements we present, most of them have been devised here, but we do not claim priority In a few cases, where the originator is known, we have appended his name to the diagram. although it is probable that others interested in fast cameras may have indepen dently thought of them

In the central column of the diagrams we have arranged illustrations of the fundamental types of Schmidt cameras and, to the right and left, some adaptations of these

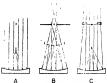

Figure 2. Spherical aberrations and Schmidt's remedy for them

types, most of which need no explanation No VI, which shows the diaphragm replaced by a correcting mirror, is shown, as are most of these diagrams, in an exaggerated form; in practice it is necessary to reduce the angle between the incident and reflected beams to a minimum in order to reduce the foreshortening effect. A perfect correcting mirror should be figured in an elliptical form but, since such a figure is very difficult to produce, we must be satisfied with an approximation in the form of a circular correcting mirror. If the aperture ratio of a camera using a correcting mirror is small, the foreshortening will be negligible, and here we have a perfectly achromatic arrangement which should be exceedingly useful in working at the extreme limits of the spectrum

When a Schmidt camera is constructed with an aperture greater than its focal length, the curves in the currecting plate become steep enough to introduce appreciable chromatic aberration. If, however, we use a thick mirror, R/2 in thickness, silvered on the back surface, as shown at IX, we increase the speed of a Schmidt camera by a factor of 2½ to 3 times, depending upon the kind of glass used, because, on passing from one medium to another, the energy-density of a cone of rays is changed by a factor equal to the square of the inverse ratio of the indices of refraction of the two media To put this in other words. since the rays, after passing through the surface of the mirror, are refracted toward the normal, they appear, as seen from the surface of the mirror, to emanate from a point closer to the axis; hence the angle subtended by an object is reduced, and the mage formed by the mirror is correspondingly diminished in size The geometrical

focal length, however, has been changed but little, and thus we can obtain the speed of an f/0.66 camera with a field and correction-plate curvature of an //1.0 camera. This is shown clearly in Figure 4, where an ordinary Schmidt camera is compared with one of the thick mirror type

In such a camera the correcting plate is placed at a distance of R/2n from the front surface of the mirror, where R is the radius of the mirror and n the index of refraction of the glass. This position is the apparent center of curvature of the mirror as seen from the mirror surface. (In all cases where the focal curve lies at the surface of the glass the photographic emulsion should have a film of oil between it and the glass, in order to make optical contact Coal-oil will be found quite suitable for this purpose)
In XII, Figure 3, we have the extreme

SCIENTIFIC AMERICAN 24 West 40th Street, New York, N. Y. form of solid type-one in which there is no medium other than glass between the correcting surface and the focus. This was first suggested to us by the late Sinclair Smith We do not know of such a camera having been made and there are some practical optical difficulties to be surmounted in constructing a solid Schmidt, furthermore, the increased absorption of the thick glass becomes important, and, since it must be sufficiently homogeneous for its purpose, such large blocks are very expensive two parts, separated by the dotted line in the diagram, should be figured separately but when cemented together they must be accurately co-axial The photographic plate could be introduced into the focal curve through a hole in the half containing the

along the axis as shown

Figure 4. Ordinary and thick nurror

Schmidt camerus compared to scale Index of refraction assumed to be 2 correcting surface, either from the side or

The difficulties of the extreme thick mirror types may be overcome by a variation of Wright's ("Amateur Telescope Making-Advanced") system, that is, by placing the correcting surface at the focus as shown in XV; but here we are confronted with two non-spherical surfaces, extremely difficult to figure in conjunction with each other An experimental camera of this type, with an aperture ratio of f'l, was constructed here, but it was not a success because the higher order aberrations rendered the images unsatisfactory It is possible that a camera, geometrically 1/4, or with an equivalent focal ratio of 1/3, would be entirely satis-

One of the neatest of all solid types that shown in XVII—the folded soli Schmidt, designed by Hendrix Here we have few practical optical difficulties, although there are four components Of the seven plane surfaces only the hypotenuse of the large prism must be worked to a high degree of precision, the cemented surfaces are sufficiently accurate if worked to a wave, because the cement, which should have an index of refraction equal to that of the glass, fills in the arregularities between the surfaces. Small errors in the thickness of the components may be rectified when adjusting the small prism during the final assembly.

The "off-axis" type, illustrated in XX, is exceedingly useful in practice because, with this arrangement, the photographic plate or film may be placed outside the light beam This system also is adaptable for visual observations. Making a single off-axis correcting plate of large dimensions is, unfortunately, somewhat wasteful of time and material, because it is necessary to figure a correcting plate of more than twice the required diameter. If more than one camera of the same focal length is required, the waste is reduced, because several off-axis plates can be cut from the original one. This type seems to be the only practical one for

mass production.

In XIX the Schmidt principle is used in the form of a microscope. Such an arrangement might prove useful for low-power work where a large field is desired, such as in microphotometry, but perhaps the most ingenious arrangement is that of Hayward, XXI, in which he suggests a thick nurror with the focal curve ground out of the mirror face, and serving as a reservoir for small living organisms. An unsilvered portion of the spherical mirror serves to admit light for dark field illumination.

The Design and Construction of Correcting Plates: The deviation, A. of the surface of a correcting plate from a plane is given by the biquadratic parabola formula

$$\Delta = \frac{x^4 - kr'x'}{4(n-1)R^3} \tag{1}$$

where x is the radius of the zone, A, a constant, 7, the radius of the correcting plate. R, the radius of curvature of the spherical introry and a the index of refraction of the glass

Now, let
$$I(n-1)R^3 = \frac{I}{K}$$
 (then (1) becomes $\Delta = x^2(\tau^* - kr^*)K$ (2)

which is in a convenient form for computation Giving & various values from -- 10 to +30, we obtain the series of curves shown in Figure 5 When A==0 we have a lens with a sharply turned up edge and flat in the center This form is one of the most

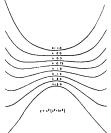

Figure 5: Correcting plate curves

difficult to figure, yet the writers have seen it recommended for amateurs! As k is increased the center rises and the edge is depressed until, when k is unity, edge and center are equally high, and the depressed zone lies 0.707 r from the center. In this form the amount of glass to be abraded from the lens surface is a minimum and it is this figure which we have found most satisfactory for general purposes; it is also the easiest to construct. When k=1.5 we have a correcting plate in which the effect of chromatic aberration is at a minimum. This is the type of correcting plate which we have used for our "thick-mirror Schmidt' cameras, several of which have been con-

structed here. When k=2 the neutral zone is at the edge of the plate and the figure becomes difficult to achieve in practice. In all plates the edge gives some trouble while figuring, because of the flexible nature of the tools used in this work, hence it is hest to make the plates at least 1" larger than the required diameter; the troublesome edge can then he masked out when the camera is assembled It is estimated that the cost of labor in making a correcting plate is reduced at least 50 percent by making a generous allowance for the edge Differentiating (2) and equating to zero,

$$x^{t} = \frac{kr^{t}}{2}.$$

This gives the distance of the neutral zone from the center, and, by substituting this value for x, in (2), we obtain

$$\Delta = \frac{k'r'}{4}K$$

the depth of the curve at this zone. With these two dimensions, (3) and (4), at our disposal the correcting plate may be rapidly roughed out to shape, the depth of the zone being measured with a suitable mirrometer

The angular field, to, of a Schmidt camera is given by the equation

$$\sin \frac{\theta}{2} = \frac{d'}{2j}$$

where d' is the diameter of the plate holder and f is the focal length of the mirror, and, in order to utilize all the light, the diameter, D, of the mirror must be

D=d 4 2d' where d is the diameter of the correcting plate. For ordinary purposes d' should not greatly exceed

The correcting plate is made from planeparallel glass plates free from strike It is very important that the plates be planeparallel, especially for telescopes used for stellar photography If the plates are not plane parallel, glost images, caused by the internal reflections in the lens, will be formed to one side of the brighter stars. (It has been suggested to us that these ghost images night prove useful in stellar photometry.) When the plates are plane-parallel these spurious images fall on the image of the star causing them. For ordinary work a high-grade plate glass, such as Caystalex, may be used, but when high ultra-violet ransmission is desired, glass such as Schott's U.B.K.5 or Vitaglass must be used A satisfactory thickness for the correcting plate is of the order of 1/40 to 1/50 of its diameter.

The plates are best supported, during grinding and polishing, on a circular felt pad which should be shrunk before use, he pad should be a little smaller than the lens. For small lenses the glass is held in position by a metal ring slightly larger in diameter than the disk and projecting above the level of the turntable by an amount sufficient to hold it in place, but not high enough to interfere with the motions of the tool. During grinding and pol ishing the plate should be rotated frequently upon the felt base. In the case of large lenses the plate is best retained on the table by means of sets of vertical spring bronze "fingers" attached to the turntable; at least six such sets should be used.

It will be noted that a certain polishing action is going on, on the rear surface of the plate, during the pollshing stage, due to

the motion of the plate upon its supporting pad which is difficult to keep free from rouge at this stage. The effect of this is eliminated, after the required figure has been approximated on the front surface, by msking the final corrections on the hack. During grinding no abrasive should reach the back surface of the correcting plate because of the protective gap between the felt and the edge of the lens. (This is the reason for cutting the felt disk smaller than the plate)

The best form of tool we have found for grinding out the zones is constructed as follows Three triants (120-degree sectors of circles) are cut from moderately stiff springhronze sheet in such a manner that the grain of the metal-that is, the direction in which the sheet was rolled -is the same in each. These sectors are then cut into radial "finto the underside of the extremities of which are cemented the grinding facets These facets are cut from unglazed ceramic tile, such as the small size used for bathroom floors. The sectors are then attached to a suitable hub and, if necessary, the fingers may be bent downward and outward, keeping the outer ends parallel to the surface of the plate.

Polishing is done with facets of moderate-ly soft pitch attached to a sponge-ruhher hase about 4" thick, the rubber permitting the tool to conform to the zonal curvature of the correcting plate. Polishing tools with a sponge-ruhher base will be found excellent for working on all optical surfaces where zonal curvature exists.

It will be realized, we think, that all hut the smallest tools are of the ring form For smoothing out irregularities in the curvature of the zones a small common tool, one quarter, or less, of the diameter of the plate may be used. This should be given a long elliptical stroke in the direction of the zone

Schmidt's method of polishing correcting plates was to place them concentrically on the lip of a shallow circular metal pan, the edge of which was ground so that an airtight seal could be made between the glass and the metal. The air was then pumped out of the pan, causing the center of the plate to be depressed; then, by the use of a spherical tool of the correct curvature, the zones were automatically polished to shape. This method is not to be recommended, however, except for mass production, when it becomes the

modus operandi. The figure of the plate may be examined during the grinding stage by dipping it into a solution of ethyl cinnimate and Xylol, mixed in a proportion of 4.1. This forms a smooth coating which has approximately the same index of refraction as the glass. After a little experience it is surprising how readily one can detect small irregularities in the curvature, or the displacement of a zone, by direct visual inspection of the form, using a good straightedge held in contact with the plate as a guide for the eye.

The Chinese mirror effect is sometimes useful in correcting local irregularities, and even in polishing and figuring plates with small curvature. The lens is here supported on suitably shaped pads of semi-cured rub-ber, such as that used for patching automobile inner tubes; the part of the lens thus supported is abraded more rapidly than the unsupported regions.

A number of methods have been worked out here for testing correcting plates, some of which will now be described. The figure of the correcting plate may be readily ex-amined with a knife-edge if one has a telescope sufficiently large to take in the collimated beam from the assembled camera, as shown in Figure 6 at A. Using this method, a point source of light is placed at the focus of the camera, and the knife-edge at the focus of the telescope. The sensitivity of this test is proportional to the square of the ratio of the focal length of the telescope to that of the camera

There a large telescope is not available for testing we can make use of a small one, in conjunction with a pentaprism or an

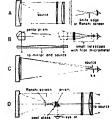

Figure 6: Methods of testing correcting plates for Schmidt types

optical square, as shown at B Here we have a small telescope rigidly set up at right angles to the axis of the camera. The optical square, consisting of two plane mirrors ounted at an angle of 45 degrees, or a pentaprism, is set up in front of the telescope on a base which may be moved across the collimated beam of light. The image of the light source is focused on the intersection of a pair of cross-wires in the focal plane of the telescope. As the pentaprism is moved across the collimated beam the image should remain on the vertical wire; any lateral motion is due to the poor figure of the optical system, vertical motions may be due to ir-

regularities in the motion of the pentaprism. An excellent test for cameras having an aperture f/5, or less, is made by placing the correcting plate directly in contact with the mirror, as at C. The test is made on the axis of the lens, in a manner similar to that used for testing a parabolic mirror in the center of curvature; that is, by measuring the apparent radius of curvature of the various zonès with a knife-edge at the focus. In this case the test is twice as sensitive as that for a parabolic mirror because the light passes twice through the lens. The formula now r; this, when both knifebecomes $\Delta R = \frac{y^2}{2}$

edge and light source move together.

A Ronchi screen placed inside the focus of a Schmidt camera will form a series of fringes on a screen placed at a suitable dis-tance from the focal point, as shown at D. By using an opal or ground-glass screen these fringes may be examined readily. Each fringe should be straight with parallel boundaries, but the presence of zones in the correcting plate distorts these fringes which are interpreted in the usual manner. The familiar Ronchl screen method of testing is excellent, also, for lenses with large aperture ratios, or where the focus is too short for the eye to focus on the equivalent plane An illuminated, small, silvered glass bead serves as an excellent point source of light for testing purposes The illuminating beam

should be concentrated on the face of the bead facing the mirror or lens to be tested. Any stray light which passes the bead should he blocked off by a suitable diaphragm placed behind it-a totally reflecting prism is excellent.

To test a correcting plate made to work in the extreme regions of the spectrum tinfrared or ultra-violet) we can construct a testing mirror of radius R' so that, in equation (1), (n-1)R'=(n'-1)R'

and thus make the tests in visual light which gives an index of refraction of n'.

There are, of course, numerous other methods of testing correcting plates, but those given here are sufficient, we think, for the average reader. It must be remembered that the plates, to begin with, must be plane-parallel, and they must be free from strike In selecting plate glass for correcting plates, sheets should be first tested with a micrometer for uniformity of thickness, and then tested for striae by holding the sheet between a small bright source of light, such as an arc, and a white screen Shadowlike streaks on the screen show the presence of these defects, and their positions can then be marked on the glass with a wax pencil I aless a large plate is required an area large enough for the purpose usually can be selected from relatively cheap glass -- Pasadena, Califor-nia, March, 1939

Till's completes the article by Hendrix and Christie. In reply to a request, the latter states that Schmidt died about four years ago. His only article appeared in Central-Zeitung fur Optik und Mechanik, Bund 52, Heft 2, and in Mitterlungen Hamburg-Bergedorf, Bund 7, No 36, under the title of "Ein lichtstarkes komafries Spiegelsystem

Because of his full occupation with important optical work now in progress at Pasadena, the senior author sincerely regrets that he will not at present find it possible to answer requests for further information.

Crystalex Pittsburgh Plate Glass Co., 2222 Grant Bldg., Pittsburgh, Pa. Schott's glass: Fish-Schurman Corp.,

Vitaglass The Vitaglass Corp., 220 Fifth Ave New York, N. Y.

The Schmidt camera gives great promise in astronomy, professional and amateur, and there is lots of work for the amateur to do with it. Heretofore a heavy discouragement in undertaking a Schmidt has been the interminable job of excavating the very deep curve of the primary—about ½" deep on a 12½" disk. It is hoped that plans under way as we go to press will nake possible the purchase of pre-roughed-out 121/4" disks.

Last April this column stated that two off-axis mirrors had been made at the Mt. Wilson shops, we learn that two dozen is more nearly the correct number,

Stellafane convention, Sat., July 22

Convention of amateur astronomers, including planetarium show and banquet, at Hayden Planetarium, New York, Aug. 19 and 20. Former day will also be Amateur Astronomers' Day at World's Fair; Professor Shapley will give a talk. A threeweek exhibit of amateurs' work will be held at Hayden Planetarium July 30 to Aug. 20.

PHOTOGRAPHY AND THE AMERICAN SCENE

R. Robert Talt

PHOTOGRAPHY has played a part in American history, a part that probably never has been thoroughly described until the production of the present book. Here is given a running story of the development of photography during its first half century up to and beyond the Civil War days. The entire book is an excellent example of the bookmaker's art, being presented on fine coated stock with a large number of half-tones, some of them fairly large reprodutions of well-known photographs of Civil War scenes Essentially non-technical, al though a few descriptions of processes are included. The voluminous notes at the end of the book will prove of great value to any student of photography. (546 pages, 7½ by 10½ mehes, profusely illustrated) > \$10.50 postpaid. -4 P. P.

ENGINEERING OPPORTUNITIES

Edited by R W Clyne

EVER so often there comes to our notice some new book which is intended to be a guide for boys who wish to enter engineer ing and for the parents and teachers of such boys. Of those we have seen, this seems by all odds the best It covers a field of 25 ingineering opportunities, the discussion of each having been prepared by some authority in that particular subject. Lach discussion gives the hackground, scope, and modern practice of one engineering study in such a way that boys and their teachers and parents may judge its potentialities as a career fut boy (Illustrated, 397 pages, 51, by 81/2 inches 1--\$3.10 postpaid -F. D. M.

TRADE MARKS AND UNFAIR

COMPETITION
By ORSON D. MUNN

A Trade Mark is an intangule asset of a business, yet its actual value may grow so large that it becomes the very foundation on which depends the whole structure of the business. Because of this fact, every business man should have available such information on trade marks as will enable him to judge with a fair degree of accuracy the destrability of any mark which he may be considering.

Here, in one handy volume, written in non-legal terms, is a simple yet comprehensive interpretation of the Federal statutes and the body of common law relating to trade marks and unfair competition.

CURRENT BUILDING

(The Editor will appreciate it if you will mention Scientific American when writing for any of the publications listed below)

A Transformation Miracle, by Edward G Budd, is a 10-page booklet which describes briefly yet adequately the amazing growth of attramined trains on American ratiroads, and the advantages which have accrued to the traveling public as a result Edward G. Budd Manufacturing Company, Phaladelpha, Pennsylvena—10 cents.

Twin Ships, by Alexander Crosby Brown, is a 90-page illustrated booklet contain ing a chronological history of the use of multiple hulled vessels, such as catamarans, for sail and steam The Mariners' Museum, Newport News, Virgina — 70 cents.

LATATTE CANERA CATALOS is a 40-page thoroughly illustrated booklet which hats a wide variety of standard products plus the complete line of Lafayette accessories Data sheets are included with information on him and paper speeds, an exposure chart, and a discussion of fine-grain development. Lafayette Camera Corporation, 100 Sixth Avenue, New York Caty.—Classic

HARDRES CONVERSION TABLE FOR NICKEL ALLOY STAFE. IS a CHILIDIOI CATCH WHICH NOT ONLY GIVES THE ALLOY STAFE. STAFF AND ALLOY STAFF. THE ALLOY STAFF AND ALLOY STAFF. THE ALLOY STAFF ALLOY STAFF. THE ALLOY STAFF.

SOUTHWARE ÉMENT TENTRE MACHINES. 18. 44-page thoroughly illustrated booklet which tells briefly of the development of hydraulic testing machines during the past decade and then goes on to show and decade and then goes on to show and decade and then goes on to show and development of the state of the sta

THE ESSENTIALS OF RECORDING IN a 22-page booklet which not only describes methods of making high-grade phonograph records in the home by the electrical process, but also lists the equipment necessary for doing the work, giving prices Allied Radio Corporation, 833 Fest Jackson Boulevard, Chicago, Illinois.—10 cents.

QUIET EMERSON ELECTRIC FANS is a folded circular which describes an entirely new line of fans for a wide variety of applications. The Emerson Electric Mig. Co., Inc., 17 East 42 Street. New York City —Gratis.

APPARATUS FOR ELECTROLYTIC CONDUCTIV-ITY MEASUREMENTS IS a 40-page illustrated catalogue which describes and lists the latest forms of equipment for making electrolytic conductivity measurements. It contains a general discussion of industrial measurements and research, and includes information on recent developments for precise measurements. Suggested combinations of equipment are illustrated and lated. Catalog EN-95. Leads & Northrup Company, 4911 Stenton Avenue, Philadelphia, Pennsylvania.—Gratie.

Ibrat, CATAGO AN HANDROOK is an 84-page illustrated catalogue covering motor and other maintenance equipment as well as electrical specialistes. Beudes the listing of equipment, there are also presented a number of pages devoted to haris on commutator care, operation of direct-current generators, definitions of electrical terms, and many engineering tables of great value. Ideal Commutation Director Co., Stromor, Ellinois.

WATER ANALYSIS, METHODS, CHEMICALS, AND APPARATIN presents estentifically sound methods of water analysis includes directions for taking samples and use of birrettes, as well as for all the usual tests made on industrial and boiler waters # H & L D Betz, 235 W. Fyoning Avenue, Philadelphia, Pennylvoma.—25 cents.

This. Patent Problem From the Viewpourt of Indistry, by Otto S Scharer,
is a 14-page compacted discussion which
pre-ents views based particularly upon expetence in the electrical and radio indiatites RCA Institutes Technical Press, Radio
Corporation of America, 30 Rockefeller
Plaza, New York City—Gratis.

LINK-BELT OVERHAD CONVEYORS is a 20page hooklet, thoroughly illustrated with plotographs showing various types of indistrial conveyors that can be used for handling a wide variety of products. Book No 1630. Link-Belt Company, 307 North Michigan Neune, Chicago, Illinois.—Gratis.

OPERATORS HANDROOK is a 96-page pocket-MED booklet designed to provide information for the users of all types of tires other than those for passenger cars. It covers such phases as tire problems, fitting the tire to the job, specifications for industrial tires, farm-service tires, load ratings, inflation pressures, and so on. B. F. Goodrich Compony, Akron, Ohio—Cratu.

LABORATORY GLASS BLOWING WITH "PYREX"
BAND GLANS is 20-page pamphlet offered as an aid to the laboratory technicum.
It consins information on the working characteristics of this particular glass, an explanation of fundamental glass blowing
operations, and recommendations of suitable
tools and equipment. Corning Glass Forks,
Corning, New York—Crais

SUCCESSFUL FARMING FOR ARSENTE OWN-IRS, by Cornelius J. Classeen, is a 52-page booklet that is directed specifically to absenter farm owners who desire to make a reasonable income from their property, Ir suggests to such owners a way in which farm incomes can be improved and property protected from the hazards of operation by interted from the hazards of operation by incompetent or irresponsible teamst. C. J. Classen, President, Farmers National Company, Omdan, Netraska.—30 centrals.

LEGAL HIGH-LIGHTS

Patent, Trade Mark, and Related Legal Proceedings That May Have a Direct Effect on Your Business

By ORSON D. MUNN, Litt.B., LL.B., Sc.D.

New York Bar Editor, Scientific American

GLASS HOUSES

PEOPLE who live in glass houses not only should not throw stones but should make sure that they do not infringe a patent recently allowed by the Court of Customs and Patent Appeals.

The inventor of a glass brick applied for a patent on the brick and on a type of building construction using it. The patent was refused by the Patent Office and by the Board of Appeals However, the decision of the Patent Office and the Board of Appeals was reversed by the Court of Customs and Patent Appeals and the patent was allowed The brick in question was a hollow glass block having at least one side thereof fluted or ribbed so as to form prisms. The prisms were so formed that downwardly slanting rays of light such as sunlight, when passing through the brick, were deflected in an upwardly slanting direction on the opposite side of the brick When bricks of this chaiacter were used in constructing a wall the sunlight passing through the wall was deflected onto the ceiling in the inside of the structure Prior to the development of the bruk in question hollow glass bricks had been employed but these bricks were not provided with prisms to cause the deflection of the light upwardly in the manner described above

The Court sponted out that the undrect highling effect caused by the prism arrangment on the new brick was not obtainable by the old type of brick. It was accordingly concluded that since the structure was now and since it produced a new result it constituted invention and that a patent should be granted. In support of its decision the Court stated.

"It seems to us that the concept of cauing defection of hight rays in the manner
which has been described was inventice." To consummate the conception and embody it
in structural form must have required calculations based upon the physical laws re
lating to high, and, finally, experiments to
determine whether the result desired had
been obtained."

AIR SPUN

FACE powder and graphite were held not to be goods of the same descriptive properties in a recent decision of the Court of Customs and Patent Appeals involving the trade mark "Air Spun." A prominent manufacturer of graphite attempted to register the name. "Air Spun" as a trade mark for graphite and the registration was opposed by a commenter manufacturer who used the same name as a trade mark for face prowder. The reasons urged in support of

the opposition were of a rather unusual hearater Thus the consence manufacturer ascerted that graphic was used in lead penits, that the pubble generally associated lead with lead pencils, and that lead, which at one time was employed in face powders and face lottons, was regarded as a harmful ingredient Because of these face is a waarzued that some customers might be led in believe that "Air Spun" face powder controlled that the pencils of the property of were permitted to one and register the trademats. "Air Spun"

The Court rejected this argument, however, and held that any dissage that might result to the cosmetic manufacturer by the reason of the use of the trade mark "Aur reason of the use of the trade mark "Aur "Spin" by the graphite manufacturer was of such a remote and speculative character as not to partly refusal to register the trade mark. It was also pointed out that the good-were of an entirely different class. that they do not look allow, were soft an entirely different class. The trade of the control of the

DISC LAIMER

One of the most unsatisfactory portions of the patent law is that portion dealing with disclaimers. The disclaimer status provides that where a patentic, through madistrience, has claimed more than his invention, he must without unreasonable delay disclaim that which is not his invention in order to reap the benefits of the remainder of his patent.

There has been considerable confusion ato when a disclaimer should be filed and ato the subject matter which should be disclaimed Today it is generally accepted that when a court of last resort has declared some but not all of the claims of a patent to be invalid the patentee has a choice of either acquiescing to the decision of the court and filing a disclaimer or of rejecting the deer sion of the court and relitigating the que tion in a different court in a suit against a different infringer. Where the patentee elects to follow the second alternative he is risking the danger that the second court will agree with the decision of the first court and hold the same claims of the patent to be invalid. in which case the entire patent will be unen forceable because of the failure to file a divclaimer within a reasonable time after the first decision. Thus it will be seen that in every instance where a portion of a patent is declared to be invalid by a court of last reaort a patentee is confronted with the none too-pleasant choice of either emasculating his patent by disclaiming some of the claims thereof or of risking the validity of the en-tire patent by failing to file a disclaimer

within a reasonable time after the first de

them. The dream has emphasized in other control as The dream has emphasized in other congret turking in the doctamer statute. The decision involved a suit for infragment of a parent on a weaking machine. In a prior case several of the claims of the parent had been declared invalid and those claims were checkaimed. In the present case the Court held the remainder of the parent to be unvalid and unacrioreable because the parent was ano involved in the prior Intigation has which the court found to be similar in acopte to one of the claims which the patterner had datediamed.

The Court held that the patentee had elected to disclaim the portion of the patent wheth had previously been declared invalid and having made that election he should have disclaimed all of the claims covering that subject matter. As a result, the suit for patent infringement was dismissed for the rather rethined reason that in fling its disclaiment the patenties had failed to disclaim everything that the should have the claimed. This decision represents one more reason to the contract of t

RUBBER FAN

THE popular fans having rubber blades which waft summer breezes at its without benefit of a protecting guard were involved in a recent suit for patent infringe-

The owner of a patent covering a fan of this character browth surcharping that a some-hal similar fan made by a competitor of the character of the patent. The patent declosed a fan having rubber blades which were accreded in a reason as the patent of the

One of the defenses rused in the out was that the mere need ruther in unking fan blades did not constitute invention. The focurit rejected this contention, pounting out that the patent related to more than the merne of ruther. It usualt the use of a flexi ble material in the making of fan blades and the supporting of the fan blades in such a manner as to give them sufficient rigidity in preserve their weddines while at the same time preserving the inherent resiliency of the material and the resulting adder/character-

In this connection the Court made the following statement

"While the more not rubber in making in his way no invention, the use of a flexible material, which might of course he rubber, in the way the patentee taught how to use it to obtain the desired results by an aching at in his way to the hold to increase its utility as a fan blade without destroying may appreciable way its inherent safety qualities, was what the patent law is designed to protect."

SCORMODEC NODERICAN

(Condensed From Issues of September, 1889)

TELESCOPE MIRROR.—"A means whereby concave mirrors of bong forous ney be reachly produced from planet-faved mirrors: in the state herewith. To make such a mirror a pan is employed, preferably nade of cast metal to be extremely radi, and with fainged edges by which it may be boiled by three equidistant bodts to the flanaged end of the tube. This pan is formed with a seat or shoulder, as shown in the sectional view, upon which there is placed a plane mirror, through the axis of which there is drilled.

a small hole adapted to receive a tube, with threaded ends to engage an upper and a lower duck, fitting on the upper and lower faces of the mirror. The hottom of the pan has a central aperture through which is passed a headed and threaded tube engaging the other tube, and the tube passing through the hottom is turned by means of a suitable wrench, to draw the center of the mirror down against its own rigidity, hending it into concave shape."

TUNNEL—"The Iludoso River tunnel, designed to gue passage for railway trans under the wide body of water that separates New York from Jersey City, is agan in process of construction. Vertical shifts were aunk near the shores of the river The one on the west shore is sixty-five feet deep, circular in section, and thirty feet in intensal diameter. The walls himse if are four feet in thickness. From these as starting points to millelism with each diverging shafts to the start of the s

MORTAR.—"A new idea in Germany is the wholesale manufacture of morars of the beat quality, to be sold to small builders and private individuals. Some 2,000,000 bbl. were thus sold last year in Berlin. This obviates the necessity of making the mortar on the ground under unfavorable circumstances and at unnecessary expense."

TUBING.... "Considerable interest was shown at the Brussels exposition in a flexible metallic tubing exhibited . . . formed by wrapping strips of metal spirally around a mandrel. The metal strips were bent over at both sides and a thin, narrow rubber band was

inserted to prevent leakage. The tubes could be bent in any direction, were perfectly tight, and were claimed to possess great resistauce to both internal and external pressures, and to be easily hundled and repaired."

ALUMINUM.—The Putburgh Connected Gazette says: Few persons are aware that an channour-making plant is now in full enterprise of the produced day. It is worth about \$4 per pound, and this is a very large single output when compared with the product of the factories in other parts of the world. The material is used for various purposes. It has taken the place of niker leaf in sign paint ing, and in that particular has proved a great sunccess."

TALKIES.—"At a recent meeting of the French Academy M. Jupman presented a note by M. G. Gueroult, in which it is suggested that by the combined use of a phonograph and an apparatus for instantaneous photography and reproduction of the pictures obtained, it would be possible to reproduce at any future time not only the speech of a person, but also liring before the audience a wide price of the person's, generates and facial expression."

PAST GLORY "In 1880, the total tonnage of the English merhant marine was 18,000,000 tons, and that of the United States 9,000,000—a tonnage four times as large as that of France. American alups numopother nearly 20 percent of the total recursts of the commercial maritime carriage of the world. France and Germany foure in this communication that the state of the properties of the foure in this communication that of the State of the State of the State of the foure in this communication that of the State of

LAMP "A new type of semi-incandrescent lamp", consists of two horizontal rods of copper, set in line with each other, but separated by a pages of about 3/6 of an use. A thin third carbon rod is set vertically, and rests upon the ends of the copper rod, forming a bridge across. The current passes through the copper rods and through the point of the carbon rod, which is thereby rendered health and the carbon rod, which is thereby rendered brilliantly incandecesent."

GIIN.—"The great 1206 inch De Bange gun excites much attention at the Pans rathbuton. It was tested on the trial ground at Galass on May 7, 8, and 9 last . The greatest range was a trifle short of twelve miles. A war also capable of carrying and discharging these weapons might be three miles out in the ocean off shore at Coney Island, and throw projectiles into the citres of New York and Brooklyn. Our war department should begin to think about obtaining some of these arms."

ELECTRICITY—"According to reliable reports, there are at present 3351 isolated electric lighting plants and central stations in the United States alone, operating 192,500 are and 1,925,000 incandescent lights each night."

OUR POINT OF VIEW

Oily Outlook

PETROLEUM, black gold of the oil more ways than one has made possible our highly developed automotive age, holds forth promises of even greater marvels in years to rome. Given a quantity of petroleum, the modern researchement produces an awe-inspiring variety of materials which, in one way or another, can militioned, even change the mode of, our daily lives And this to does with what, in the future, will be considered to be a meager knowledge of his subject.

Meager though present-day knowledge may be, developments in the field of petroleum research make it possible for the technologist with a flair for prophesy to give us a well-founded glimpse of what the future holds in store. Thus, Dr. A. E. Dunstan, British petroleum technologist, did not stretch facts beyond possibilities when he visualized the petroleum home of the future where even the food served will, in part at least, be derived from petroleum. Briefly described, Dr. Dunstan's dream home will have a roof of petrolenm-base tile and walls of synthetic glass or hollow brick, while doors, partitions, windows, and even furniture will be fashioned of some form or another of petroleum-extracted plastics. Decorative effects will be obtained with similar plastics, aided by brilliant or subtle colorings skilfully obtained from through the use of petroleum dyes.

The people who live in these petroleum-created homes will even wear clothes whose origin will lie in petroleum. Fibers made from a petroleum base will be woven into fabrics that, in turn, will be colored with dyes from the same source.

Synthetic food from potroleum will constitute at least a part of man's det. Dr. Dunstan believes, and backs up this thought with a reference to the fatty acids that can now be extracted from petroleum. These substances could very likely be combined with other petroleum derivatives to form foods that would equal in nutritive value the animal and vegetable fats of today.

Whence will come the vast supplies the program? Alarmsts would have it that our petroleum reserves will be exhausted shortly. But improved methods of reclaiming oil from Mother Earth, new fields being explored, more efficient utilization of petroleum, are all pushing further and further into the future the time when the point of exhaustion will be reached. In the meantime, it is pleasant and inspiring to let the mind wander through new fields to a region where today's home will be yesterday's potential crankcase filling.—d. P. P.

Hypergeometry and Hyperperplexity

OME months ago-as long ago as March, in fact this journal published an article entitled "Visualizing Hyperspace," in which was discussed a fourth dimension of space and a method of visualizing exactly what this kind of space would look like if there were such a thing. From time to time since then the editors have received inquiries from puzzled readers who appear to be confused about a variety of questions suggested by this article. Is not time the fourth dimension? How do the mathematicians know that there are more than the three common dimensions with which we are all daily familiar? How many more dimensions are there and, anyway, aren't a good many of the mathematicians just a bit "teched"?

First, icgarding time as the fourth dimension: True, time does figure in the so-called "space-time continuum," but not as an extra dimension of space.

Next, how do they know there are extra dimensions of space? They don't! They play with them, however, just as if they did exist. All the mathematician does is to take the algebraic formulas of analytic geometry whech the has any piech to three-dimensional space and go on developing them in the same way for added dimensional. It is a game but the matter ends there—that is, so far as they know, for it is of course dogmatic to assert positively that there are no extra space dimensions. All we can assert is that, if there are, man has never rune across any real ones.

The mathematican is a whimsued fellow who thoroughly enjoys deliberately creating a make-believe and then proceeding to show what would be the case of it were true. He does this sumply because it is such fun. His brain is active and can't help playing these little games. And, at that, there is no crime in extending his logical processes out mathematical transfer of the companion of the sident throughout—that is all science

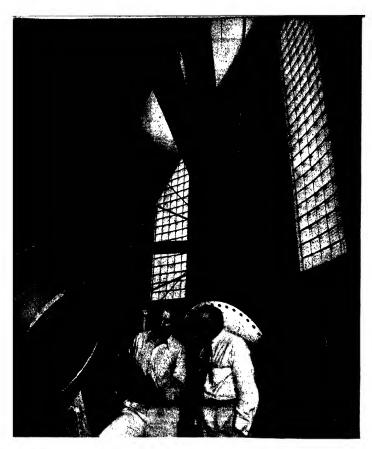

What probably confuses the puzzled non-mathematician is the fact that the mathematician uses for his excursions into the imaginary the same word he uses in connection with something he and all the rest of us knows to exist; that is, "dimensions" If he would call them something else the confusion would promptly end for most of us.—A. G. I.

Trees

TO say that all the lumber cut in the United States during the past 135 years would make a solid cube a mile on each dimension would not impress many people. We just don't visualize the enormity of such a cube. In terms of board-feet, however, the quantity shows up clearer and we begin to realize the inroads we have made on our tumber resources A cubic mile of lumber would total considerably more than 1700 billion board-feet. Yet this is only a fraction of the drain on our forests, for the vastly increased demands for pulpwood-for paper, rayon, and related products-has denuded many thousands of once heavily forested acres And the continual process of cutting firewood and of clearing wooded areas for farming, as old farm soil wears out and is abandoned, is taking its toll.

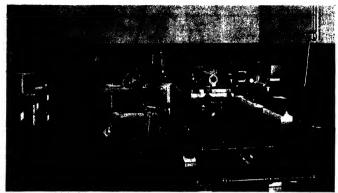

Conservationists are now, therefore, cheered by the news that farmers have more than doubled their tree-planting since 1935. The Forest Service of the Department of Agriculture reports distribution in 1938 of over 55 million tree seedlings and transplants as compared with a distribution of only a little over 26 million in 1935. The law providing for such distribution by the Federal Government in co-operation with state governments-the Clarke-McNary Law --- is not so new that it would provide explanation for this spurt in planting. It dates from 1924. The indication is that some other factor is involved, and we'd like to feel that it is a nascent consciousness of our sins of the past and of the great value of trees in our national economy-trees standing alone or in woods, forests, or wind-breaks.

The timber companies and the paper mills have that consciousness and are doing their share by reforesting as fast as they cut. New farm planting, if the dea continues to grow, will round out the cycle and assure maintenance of a continuing supply of wood for all purposes. New growth will be slow in maturing, of course, but we certainly must have reached the point where the patience should rule—after our years not of impatience to grab, before omeoneneelse did, the golden profits from Nature's bounty of trees.—F. D. M.

WITHIN THE HOUSING OF A GIANT ATOM SMASHER

TO "smash" atoms they must be bombarded with high-speed particles. One way to give particles high speed is with the cyclotron, while another is by means of an electrostatic machine. Better results are had if this machine is aperated in an atmosphere of compressed gas, and this has led to the installation of atom smashing equipment inside very large steel tanks to permit control of this factor. The photograph shows the exterior of the huge container of the Van de Craff generator now under construction at the Carnegie Institution of Washington, inside its Insulex glass block housing.

Eyes That See Through Atoms.

(In Two Parts-Part One)

THERE exist a few scientific instruments which, though they have contributed directly to the establishment of no vast new factories, and are never sold over the counter, are of incalculable value to mankind. One of the most powerful and useful of these instruments is the spectroscope; indeed, Henry Norris Russell has called the spectroscope the Master Key of Science. It appears to be true that with this talented instrument scientists have succeeded in unlocking more secrets of nature than with any other single device. Though comparatively simple in its structure and operation, the spectroscope gives answers to an incredibly wide variety of questions merely by dissecting a beam of light and separating this into its component colors.

Is life possible on Mars? Ask the spectroscope. Is a certain painter's ill-ness caused by lead poisoning? The spectroscope can tell. How much does the core of a helium atom weigh, and how much that distant star? Does this greenhouse contain the correct amount of carbon dioxide to support plant life? Of what is the tail of a comet made? How many electrons are there in an iron

atom? Is this the sweater of the burglar who crawled through that broken window? How hot is the Sun? Thousands of such questions are being asked from time to time, and are being answered correctly with the aid of the spectroscope.

ANY atom or molecule will emit light if it be struck a hard atomic blow, and all light originates from atoms which have thus been atmulated by heat or electricity. Since any material object—a starp, a drop of blood, a speck of putty object can be induced to emit light by heating it until it becomes an ineandesent approach of atoms, any material structure of the composed of atoms, any material structure of the composed of atoms, any material when the composed of atoms, any material with the composed of atoms, any material with the induced to emit light by heating it until it becomes an ineandesecret vapor. The light which is thus emitted carries inevitably in itself many secrets concerning the atoms from which it originated. It is the function of the spectroscope to analyze this light, and thus lay bare these secrets for the eye of science to read.

The chemist finds that a tiny pinch of salt needs more than a bathtub full of water in which to hide from the ferreting eye of the spectroscope, and he uses this instrument regularly to detect and measure minute traces of impurities in the materials with which he works. So bright is the light which the atoms in a small speck of metal can emit, that a piece of brass the size of a pinhead will serve for a complete determination of the presence or absence of 70 of the chemical elements. and none will be overlooked which is present in an amount as great as one millionth part of the whole. In fact, at least ten of the chemical elements were originally discovered with the spectroscope.

Atoms which are to be studied with a spectroscope need not be anywhere near it, for the light which they emit can travel a billion miles across space and still deliver up its secrets when captured

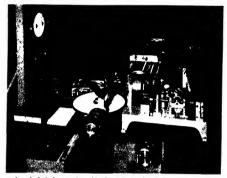

and analyzed. The astronomer is thus enabled to analyze the materials of distant stars, and has learned that even the farthest visible nebula is composed of the same atoms that we know on earthdust similar to dust across the vast stretches of the cosmos. More than three fourths of the discoveries of modern astronomy have been made with the spectroscope, and no large telescope is considered complete without one to sort out the light it gathers. Nor is the spectroscope merely an analytical tool, for with it stars and nehulae can be weighed, their temperatures taken, their speeds through space measured, and the courses charted of their lives and deaths.

To the biologist and physician also the spectroscope is invaluable, for with it such complicated molecules as those of vitamins and hormones can be studied. and metallic poisons can be detected in the blood long before they accumulate in amounts sufficient to be harmful. If the human body is analyzed down to its constituent elements, almost every kind of atom is found, but many are present in extremely small amounts. Which are essential to life and which are merely incidental? For example, little copper is found; too much copper is poisonous; yet some copper must be present if life is to continue. How much copper is too much, the spectroscope is helping the physician to determine. The same question must be answered for numerous other kinds of atoms.

other kinds of atoms. Drugs also can be studied with the spectroscope. In cases where cocaine possoning is suspected, a few drops of fluid taken from the spine of the patient can be diluted and the cocaine content can immediately be determined from its light absorption. To draw enough fluid to analyze chemically might harm the nations.

ENGINEERS find the spectroscope useful also. With it they can look made the cylinder of an engine while this is in operation, and study the burning and explosion of gases and the propagation of pressure in the cylinder. A plug of metal is cut from the top of the engine and a thick window of clear fixed quartz is inserted in its place. Through this window comes enough light to enable the spectroscope to establish the temperature of the flame at any metant, and to give analyses of the composition and rate of burning of the fuel.

Even in crime detection the spectroscope is useful, and it has had its day in court in a number of lawsuits. In one case, gasoline which exploded in a sewer was traced to one of a dozen filling stations in the neighborhood from which it might have leaked, by using the spectroscope to show that the gasoline found remaining in the sewer

A newly devised automatic machine for measuring the wavelengths of the light producing spectrum lines, directly from the positions of the lines on a spectregram. The spectrogram is clamped on the carriage in rear, the projection affectoscope above it throwing the spectrum on a screen in the center of which is a all which admits the light to an electron multiplier. The carriage is moved by the lead-acress above, and the dial geared to this reads in nearterm

absorbed light identically with the brand sold hy the station. The G-men in their government laboratories use the spectroscope regularly, as do workers in the various state criminological laboratories.

The spectroscope is thus at once, a powerful tool for analyzing matter; a super-telescope, and a super-microscope; a super-specdometer, thermomerect, tape-measure, and clock. In each role it exceeds in range and power the more common forms of these devices. This it can do because it attacks fundamentals; it studies the world and the heavens in terms of the very atoms of which they are made, and these atoms in terms of the energy which is their very life.

The foundations of spectroscopy were laid by a 24-year-old boy. One day in 1666 a young student, later to win fame as Sir Isaac Newton, threw the first purposefully produced indoor "raın how" on the wall of his bedroom. Newton thrust a prism into a beam of light which was shining through a round hole in his landlady's windowshade, and saw that the prism split the white light up into a bright spectrum of colors. By so doing he came breathtakingly close to inventing a spectroscope. If the sunlight had entered through a crack in the shade instead of through a hole, and if Newton had turned his prism so that its base was parallel to this crack, and had inserted a pair of lenses into the beam, he might have noticed dark streaks or lines running across some of the colors on the wall. More than a century elapsed, however, before Joseph von Fraunhofer designed a spectroscope which would separate light into its ultimate purity of color, and observed these dark lines in the spectrum.

Despite its tremendous analytical powers, a spectroscope is really a simple instrument, and it has no moving parts to wear out. Light to be analyzed is sent into it through a narrow slit, and then passes through a prism or similar device which separates the different waves of light in accordance with their lengths. Waves of each particular length are sent in a particular direction, where they can be observed with a small telescope. The lenses in this telescope serve to heap similar waves neatly together in one pile, where they appear as a line of colored light, an image of the spectroscope slit in light of utmost purity.

THE great power of the spectroscope arises from the fact that under sufficient provocation all atoms and molecules emit light, and each of the kinds of atonis which make up our earth-iron and hydrogen and sodium and more than fourscore others emits light of certain wavelengths and those only. Since light waves are identical with ultra-short radio waves, under proper stimulation every atom becomes in fact a tiny short-wave radio transmitting station. When a radio set is tuned to a certain wavelength a peak of sound intensity is heard if some station is broadcasting on that wavelength; a

spectrum line is the peak of light seen at a certain wavelength because an atom is broadcasting on that wavelength. The millions of atoms in a finner or electric are broadcast on hundreds of frequencies at the same time, but the spectroscope can be tuned to all these wavelengths simultaneously, sorting them out so that all can be observed together without mutual interference.

Though the waves which the atoms emit bring no purposeful message, they tell much, and by literally reading

1,000,000 separate spectrum lines have been distinguished all told, and most of these have been distinguished all told, and most of these have been identified as caused by the light which comes from one or another of the various kinds of atoms and molecules of which matter is composed. Since one or two carefully measured lines one or two carefully measured lines will serve to identify the atom which emitted them, it thus becomes almost impossible for an atom to mask its identify it is light can be sent through a spectroscope.

The patterning of lines in a spectrum

A large diffraction-grating spectrograph. Light which comes through a slit at the far side of the circular track, just to the left of the center, is spread by a diffraction grating in the black box at the right sround the circle as a spectrum. Photographic plates are placed in proper positions to record the lines

between the lines (to seven figures, in fact) the physicist has been able to deduce many facts about the atomic world from the broadcasts which originate there. Most important is the identification of sending atoms merely by noting the wavelengths on which broadcasting is being done. Just as an experienced radio listener knows that he is hearing station WZZZ when he turns the radio dial to 422 meters and hears any sort of noise, merely because WZZZ is the only station which broadcasts on that wavelength which his set will pick up, so a spectroscopist knows that he is looking at light from sodium atoms when he sees the familiar yellow light of the sodium flame, because sodium atoms broadcast on the yellow wavelength 0.5893 micro-meters. (This is usually written by the spectroscopist 5893 angstroms. Ten billion angstroms is one

The spectroscopist can be even surer of his station identification than the radio listener can, for each atom broadcasts not on one wavelength alone, but on a whole group of wavelengths. Iron atoms, for example, when made sufficiently hot are found to produce more than 20,000 spectrum lines. More than

s a language which the spectroscopist has gradually learned to read clearly. As the series of irregular black marks on this page conveys certain ideas to a reader, so the unevenly spaced lines in a spectrum convey to the scientust flashes of information—here is iron, here arenic, here are lines of copper and lead. Some of the lines are brighter than others, so the light can even be made to tell how many atoms of each kind are broadcasting—here is a great deal of iron, here a little arsenic, here too much copper in this lead.

Since the spectroscope arranges the spectrum lines in order of wave-length it is not necessary that they be seen in color, and they can therefore be photographed and later identified from their positions on the resulting spectogram. This method of observing spectra is now commonly used, both because the records thus produced can be studied at leisure, and because many spectrum lines are found in the ultra-violet and infra-red regions where they cannot be seen but can be photographed with ease. When a camera is thus used in combination with a spectroscope the resulting instrument is called a spectrograph.

Most small spectrographs contain a

prism to split the light which passes them into its constituent wavelengths, but large instruments use a more powerful device, a scientific light-sieve called a diffraction grating. This is usually a highly polished mirror on which as many as 200,000 sharp, parallel scratches have been accurately ruled with the point of a diamond. These narrow scratches, when evenly spaced 20 or 30 thousand to the inch and accurately placed to within a thousandth of the thickness of a hair, sort the light waves into spectrum lines without the use of auxiliary lenses. Prisms must be made of transparent material: glass serves for visible light, but quartz is needed for ultra-violet and rock salt or some similar material for infra-red light. A diffraction grating ruled on a mirror has the advantage that it can be used with waves of any length, within reason.

LARGE diffraction-grating spectro-A graph requires a vast, vibration free room to house it, and can throw light into a spectrum stretching a hundred feet around a huge circle. Such instruments are giants compared with the most common spectroscopes, small brass tubes on tripody familiar in elementary science laboratories. The positions of spectrum hues can be determined to within 1/25,000 of an inch, and when such precision is attained the length of the light waves is determined to one part in 3,000,000. Since the light waves are themselves only about 1/50,000 of an inch long, their lengths can thus be found to within a few trillionths of an inch-a billionth of the thickness of a

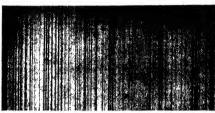

When a spectrograph is used to determine which kinds of atoms are present in a given sample of material, the sample is vaporized and a discharge of electric current is sent through it. The simplest method of accomplishing this is to strike an electric arc between two pieces of very pure graphite, and insert into this arc the speck of nietal or clot of blood which is to be analyzed, so that it is burned to nothingness. This burning tears the molecules of the material apart, separates them into their constituent atoms, and pounds each atom so hard with a deluge of electrons and other atoms that it emits the light which reveals its identity.

Suppose that a manufacturer of watches finds that a competitor is using a new hairspring of remarkable quality. This spring must be duplicated or improved on at any cost, but what can it contain that confers on its student her new temper and elasticity which are so desirable? If a chemist is to analyze the spring by ordinary means he must buy several dozen watches, extract their tiny springs, and then guess which substances are most likely to be involved, so as to select the proper

chemical reactions to carry out. He must dissolve and mix and scrape and weigh his materials with the greatest of care, for one single atom of a new alloying material to every 100,000 atoms of the watch-spring material may be responsible for conferring the high quality, and these are easily lost in a tiny sample.

How much more directly can the problem be attacked with a spectrograph! Now the chemist need merely strike an electric arc between two pieces of graphite, insert a small section of the extra-pure, 1000-proof gold which is the basis of the currencies of many countries is found to contain much atomic dirt under this revealing eye which sethrough atoms, and if the average is like the samples which have thus far been measured, dross of various kinds totalling more than \$1,000,000 in supposed value exists in the gold of the world.

An entire freight tran filled with pig-iron can be tested in a few hours by a spectroscopist dragging electric wires behind him as be proceeds from car to car, and carrying a small spectroscope

A typical section of a spectrogram taken by means of a large diffraction grating. This example shows the characteristic spectrum lines as emitted by iron

spring into the flame, and let the flash of light which results enter his mstrument and be recorded. When the plate is developed it shows hundreds of spectrum lines, and from these can be selected those which are known to arise from each kind of atom. It is but the work of a few moments to identify lines of iron, copper, chromium, nickel-all common in springs of one sort or another. But here are some lines which belong to hafnium-there must be hafnium in the spring! That no metallurgist or clicnist would have guessed that hafnium would improve a hairspring is of no consequence, for the hafnium is there, it is the only new element present. and the springs are strong and supple.

ALMOST any material can be burned in the bilistering 9000 degrees, Fahnett, of an electric are, and if a material can be burned its metallic constituents can be determined with the spectrograph, whether it be a sample of blood from a patient suffering from lead poisoning, a drop of condensed milk thought to consum more than one part of corper in 3,000,000 parts of order of the suffering condenses of the suffering condenses of the suffering collected within kinn pater. Since it is not necessary to know in advance what kinned of atoms are being looked for, 70 kinds of atoms are being looked for, 70 kinds of atoms can be tested for in one sensestion.

No metal has ever been made so pure that the spectroscope could not find impurities in it. Even the superfine, in his hand. Opening a car door he clips a wire to a sample pig, strikes an electric are between this and a harof pure ron he carries, and observes the light in the spectroscope. If certain inpurity lines are brighter than a standard which his instrument shows, that pig contains too much inpure metal, and he passes to another. By properly selecting samples at random the whole trainload of iron can be tested without bothering to unload it.

Amounts of metal so small as to be difficult to detect chemically are often of great biological importance. Why, for example, do the livers of scallops concentrate cadmium?

A little copper is good for the digestion, but too much is not. In areas where many cranberries are grown, sprays have for years been used to kill pests, and the government at one time feared that the soil might have become so saturated with copper from these sprays that the cranberries might be absorbing more copper than would be good for the consumers. So cranberries, cranberry jelly, cranberry juice, dirt from cranberry bogs, and cranberry stems and leaves were all separately consumed in electric arcs and forced to reveal their conner content to the discerning spectrograph. Fortunately the instrument announced that all was well.

Very small amounts of lead or arsenic can do great damage to the human body, and lead poisoning is one of the greatest hazards of industry. Lead fumes are

found in some mines, and in storage hattery and paint factories. Unless some care is taken to protect workers in these industries the amount of lead in their bodies may slowly rise past the danger point, and once this point is passed the resulting diseases are very difficult to cure. It is therefore important to keep a constant check on the lead content of the blood of such workers. By placing a few drops of blood from a worker in a tiny carbon cup and striking an electric arc to this cup, the blood can be vaporized almost instantly, and any lead atoms present will emit their characteristic light, which can be identified with a spectrograph This light being recorded on the photographic plate, a series of samples of blood containing no lead, but with varying known amounts of lead added to each sample, is burned and has its spectra recorded. The spectroscopist matches the intensities of the lead lines in the worker's blood with those in some of the samples whose lead content is known, and thus can measure amounts as little as one atom of lead to 1,000,000 molecules of blood. If a person be allowed to sleen for one night in a freshly painted room a definite, though harmless, increase in the lead content of his blood can often be observed with the spectrograph. Nor is this sensitivity confined only to lead, for any one of the nearly 70 other sensitive chemical elements can be determined as readily

That two or three parts of aluminum or or lead can be detected readily in or lead can be detected readily in 10,000,000 parts of lobster or condensed milk may seem unimportant, since such concentrations are below the toxic limits considered dangerous to health. Yet, obviously, tests on the rapidity with which the internal coating of a can dissolves in foods stored within it can be made easily and quickly when such sensitive methods of detection are swallable.

Chocolate and chewing gum manufacturers use spectroscopic analysis of maure that the lead content of their products is below the limit set by pure food laws. Have the areasic and lead been properly removed from sprayed foods before canning? Is beer kept in cans dissolving anything more from the container than it would if kept in bottles? The spectroscope gives an easy, sure, and quick means of deciding,

So we find paper maintacturers who want to discover the source of tiny black specks in their spotless while product, producers of bakery equipment who wonder if their new coating compound for pans will contaminate the dough, park-plug manufacturers who wish to study the effect of minute amounts of alkali metals in improving sparking, all finding the apertoscope helpful.

. (To be concluded)

FIVE COMPANIES PRESENT: SAFETY

Superior Safety Glass... Four Times Safety Factor, Five Times Elasticity of Old Product... No Fogging... No Break-away... No Splinters

AMERICA'S 25,000,000 comfort-conscious motorists have grown safetyminded to such a degree that they are quick to acclaim the development by science and industry of some noteworthy contribution that makes the automobile a safer mode of transportation.

Such a contribution is the new, lustrous, high-test safety plate glass which graces many of the sleek 1939 model

automobiles, adding greater safety and vasibility. The glass has four times the safety factor and five times the elasticity of the old product. It was developed during six years of intensive laboratory experiments by five large industrial firms at an aggregate expenditure of more than \$6,000,000.

Sharing in the development of the product, which has been made available at no increased cost, are E. I. du Pont de Nemours & Co., Inc., Libbey - Owens - Ford Glass Co., Monsanto Chemical Co., Pittsburgh Plate Glass Co., and the Carbide

sun. This enables the glass to retain its high visibility. Resilience of the glass is unaffected by extreme ranges of temperature, making it equally safe in summer and winter. It is easy to cut, facilitating replacements for damaged areas.

Statistics show that more than half of the injuries resulting from automobile accidents in the past have been

At right: Two research men stretch a plece of the glass "sandwich" filler to show its resilience. Above: Girl work-ers make the "sandwiches" by inserting a sheet of the polyvinyl acetal resin between sheets of polished plate glass

and Carbon Chemicals Corporation.
In perfecting the new glass, the
laboratory technicians made as product
that defies deterioration and discoloration, either from seepage of moisture
and air into the "sandwich" plastic
filler between the two sheets of plate
glass, or from the actinic rays of the

attributed to flying glass. This danger is further lessened by the new glass, because if it is broken by the impact of an object, the pieces adhere firmly to the plastic "sandwich" filler and do not fly about the car.

Because of its resiliency.

the new glass supplies a cushioning effect when a body or head is thrown violently against it. There is greatly lessened danger of a fracture of head or limb as the glass give readily and absorbs part of the shock. To test this feature, one of the research laboratories employed a professional stunt man to batter his beld head against

Repeated hammering on the new glass merely powders the surface

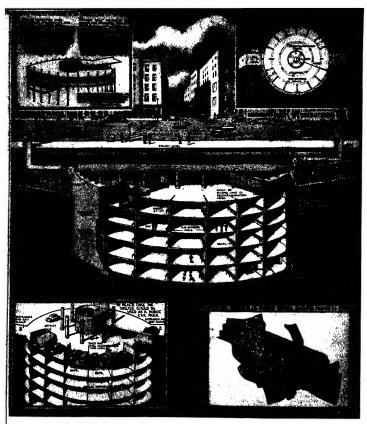

a plate of the safety glass. In repeated demonstrations, charging into the glass like a football player making a tackle, the man cracked the glass with his head but received no injury

DESPITE its greater resistance to the breakage from sudden impact, the breakage from sudden impact, the probability" of the new glass enables a passenger, trapped m a car equipped with it, to push the glass out of its frame as a means of scape When the glass is broken up by hammering it can be rolled up like a rug without the particles of shattered glass pulling away from the plaste filler.

The plastic, or "sandwich" filler, is the principal factor in the success of the new glass. Although it is made under several trade names, the plastic has one chemical common denominator polyvinyl acetal resin.

In the ten years that followed the first general use of lamineted safety glass, alaboratory technicians have bent every effort to produce the features which are dominant in the new high-test glass. Vinyl plastic is resistant to moisture, which makes is unnecessary to seal the edges. It will not separate from the glass under impact or when the glass is cracked or broken. Replacement areas are cut by seoring and cracking, drawing the glass away from the plastic, and cutture, it with a razor blade.

The new plastic may be produced either by calendering or extruding. The first method involves rolling and pressing out sheets of plastic, and the second forces the plastic at a doughly consistency through a narrow orifice. The resulting sheeting is quickly cooled.

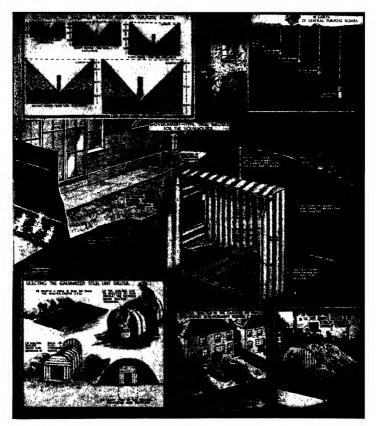

Bombing Raids Will Find London Prepared

NoT long ago a writer facetously pointed out the irony NoT long ago a writer facetously pointed out the irony in large sections of the world. Primitive man (he reminded us) lived in caves or holes in the ground, but as he achieved crilitation he came out into the air and sunshine. Down through the ages he progressed, built great cities, mastered the secrets of the world about him. He rose to new and greater triumphs until he finally left the dirt and took to the air, glorously happy in his goddlied genius. And then the cycle suddenly begins again. One of man's latest and most spectacular achievements turned, like Frankenstein's monster,

upon its maker and sent him scuttling back to holes in the ground—modern, civilized troglodytes.

The analogy was interesting, the irony real, but the aforesaid writer intended only to provide a bit of humor to offset the seriousness of air hombing dangers. They are serious, indeed, as many millions of Englishmen will testify. London knows something of what may happen when and if enemy bombers fly over the city. Shanghai and Nanking, Madrid and Barcelona—current and recent brutalities—have provided the object lessons. But they are not enough, and London surmises many things more, takes no chances, provides against

many contingencies. Now London stands determined, methodically preparing against the day which the world hopes will not come. Intensively, the city and the surrounding country make their plans for lessening the danger and destruction of an air raid, having made up their collective mind to go back to earth, literally, should bombing planes arrive.

A bombing raid over London would be no half-hearted fair. There is no doubt that the enemies of Britain would stage a monster raid—or series of raids—in the hope of gaining a smashing victory. However this night affect the population, psychologically, and how great the destruction of property might be are besided the point at the moment; whether any great number of civilians might be killed would depend upon how well bomb-proof shelters are distributed through out the areas involved. Plans have been made, considered, and discarded and other plans made up for large underground shelters that will house the multitudes during raids. On the opposite page is one suggested design of a structure which would be very effective, and it has the added merat of being useful during peacetime as a public car-parking space. Conceivably some of the large shelters may be built to this design or some modification of it. On this page are shown several views of one of the back yard shelters for residences. There are a number of variations of this type, protecting only against concussion and flying debris, being installed all over the threatened area. The inserts on the two pages show various details. This drawing is published through the courtesy of The Illustrated London News.

RIVER MODELS OUTWIT NATURE

NATURE poses no challenge more baffling to man than the one offered by flowing water. The enigma of flowing water is made the more challenging because it is presented before man's very eyes. Man can observe water in motion; he can photograph it and record certain of its physical dimensions; but he cannot explain what he sees and records. The road to geometry is indeed a royal boulevard compared to the byways which must be traversed by the hydraulic engineer

The sad fact of man's mability to rationalize the phenomena of flowing water has not obviated the equally sad fact that often he must do something about those phenomena. Lands must

be made safe from flood. rivers must be made navigable, erosion must be checked, and so on. There are problems to be solved, whether or not the means for rational solution are at hand. Furthermore, the hydraulic engineer has not the advantage of being able to bury his mistakes. If the levee is built too low, the flood comes with redoubled fury; if the dike is built in the wrong place, the river steamer and its cargo end up on a sandbar. Having made it difficult to win. Nature nevertheless has not neglected to make it costly to lose.

When rational solution fails, man resorts to solution-by-trial. He calculates

things to the best of his ability, tempers, and is calculations with judgment, adds a silberal factor of safety-ignorance, build has structures, and hopes for the best. If calculations, judgment, and luck are agood, the structures stand and serve their purpose; if luck or other factors are bad, there is a flood or an unnavigable channel or a dangerous erosion. Occordon bad the process of solution-by-trial obviously is expensive—expensive in the way of a disaster at worst, and expensive in the way of a disaster at worst, and expensive in the way of over-design at best.

Since the solution of hydraulic problems must, in the main, be by the method of trial (and error), it is idle to think of such problems in terms of absolute economy; rather, the hydraulic engineer thinks in terms of relative economy. And it must early have occurred to him to Miniatures of Rivers, Harbors, Dam Projects Solve Flood and Flow Problems... Considerable Design Ingenuity Involved in Model Making

By PAUL W. THOMPSON

First Lieutenant, C E, and Director, The U S Waterways Experiment Station

wonder whether the trial-and-error process might not be more economically accomplished if applied not directly to the waterway in question, but rather to a small-scale replica thereof. When that thought occurred to some early hydraulic engineer (could it have been during the conception of the Roman

A model of the river through Johnstown, Pennsylvania, by means of which a very serious flood problem was solved

aqueducts?) the now-flourishing science of analyses of hydraulic problems by means of small-scale models was born.

Today, few important projects involving the flow of water are undertaken without benefit of model-analyses. That statement is a paraphrase of the comments with which the English scientist, Sir Osborne Reynolds, concluded the account of his pioneer model study of conditions in the River Mersey in 1885. Sir Osborne's observations had convinced him that it would be "madness" not to take advantage of the small-scale model in designing any important project. The hydraulic world by no means flocked to get aboard the Reynolds bandwagon; but now, 50 years later, that world has practically accepted the Reynolds point of view. By the turn of the century, the German hydraulic engineers were model-minded; whereas, in America, the U. S. Waterways Experiment Station—now the largest of the world's hydraulic laboratories — has been in active operation for more than nine years.

What, then, is the small-scale modelthis tool which, while not eliminating

the necessity for solution of hydraulic problems by the method of trial, nevertheless enables the hydraulic engineer to do his trying and erring at relatively little expense? Briefly, the smallscale model, as utilized in hydraulic engineering, is a replica which acts like its prototype. The verb deserves the emphasis, for the essence of model-analysis is action. There is a technical expression covering the thought: dynamical similitude.

THE purusit of dynamical similitude permits of no side diversions. It demands compromises and apparent contradictions. Thus, in getting a model to act like its

prototype, in grandele, was minerally prototype, in frequently in necessary to take steps which presided for a lade and the steps which presided for a lade and the steps of t

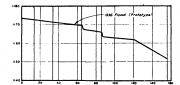

This distortion in the model' physical dimensions and appearance is a necessary evil, force on the experimenter by such hard facts as limitations of available materials; conflict of various forces; necessity for depths not less than certain minims; necessity for conomy; and other considerations. The model, in fact, represents a series of compromises,

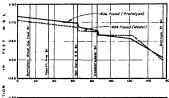

an assembly of components in which one distortion compensates for another. The fact that the experimenter must distort, say, his model bed material (by using some material, such as crushed coal, which is available but is too heavy) makes it necessary for him to distort his velocities (by making them higher than they should be); and the fact that he distorts his velocities makes it necessary for him to distort his model roughness. The thought may be conveniently expressed by stating that the model-as-itshould-be is quite a different article from the model-as-1t-18.

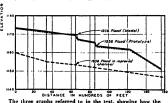

Consider again the model of the Ohio River, mentioned before Rational analysis does not even suffice to make that model act like the Ohio River, (In fact, were rational analysis equal to that task, probably it also would be equal to the task of solving the prototype problem and thereby the model study would be unnecessary) How, then, is it established that the model does act like the Ohio River? The simplest way to answer that pertinent question is to let it answer itself by means of an example.

One of America's critical flood problems has existed along the Conemaugh River

and its tributaries at Johnstown, Pennsylvania. The great flood of March, 1936, was followed by a project aiming to increase very materally the capacity of the Johnstown channels. The project moviews deepening the present channels, widening them, and, to some extent, realigning them. Details have been resolved by means of the small-scale model shown in an accompanying photograph. All horizontal dimensions on this model are 1/200 and all vertical dimensions are 1/80 of the corresponding prototype dimensions. Thus, the model-river is

The three graphs referred to in the text, showing how the model reproduced the 1936 Johnstown flood and the height which the same flood would reach in an improved channel

relatively deep and steep. Meanwhile, the areas enclosed by tin walls represent city blocks. Certainly, the model doesn't look much like its prototype. How, then, is it established that the model acts like its prototype?

Consider the accompanying graphs. The solid-line curve in each graph represents a known event: the highest elevations reached by the water during the 1936 Johnstown flood. No conjecture or calculation enters that curve; it is compiled from gage heights actually observed and recorded. The dashed-line

curves also represent data actually observed-but on the model, not the prototype In each case, there was being discharged through the model quantities of water corresponding accurately to the quantities which deluged Johnstown in 1936. The experimenter reasons that, were his model acting correctly, the dashed and solid lines should coincide He takes steps to obtain the desired coincidence, these steps consisting chiefly of roughening and smoothing operations. His progress the middle and lower graphs. The latter he accepts as satisfactory, and, secure in the belief that his model is acting correctly, he proceeds to the testing of the proposed plans. Incidentally, having successfully adjusted (or "verified") his model, the experinienter's worries are largely over Figuratively speaking, the testing of plans involves only the turning of a crank on a machine which it has taken months to build, calib-

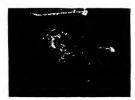

rate, and adjust.
(As a matter of interest,
not strictly pertinent to the
discussion of verification,
there is plotted on the lower
graph data indicating the
effectiveness of the improvement plans. This curve represents the crest of a flood

identical to the one of 1936 but occurring in a channel like the one proposed,)

IT will be observed that the anallscale model is a very practical instrument. That is, it is designed and adjusted so as to aid in solving a specific problem—such as the flood situation at Johnstown. It contributes only in relatively minor, degree to the advancement of abstract science. It is, in fact, only a semi-sevenific instrument. That being the case, it is found not in institutions devoted to the development of fundadevoted to the development of funda-

Model analysis of a spillway problem. The object of the engineers was to reduce water velocities and eliminate dangerous areoin oblow the dam. At the left, velocity was high and scour so had as to cause much crotion. The model was then modified to produce lower velocity (right). Result was negligible erosion

mental truths, but rather in agencies charged with the prompt accomplishment of real projects. Thus, the Bureau of Reclamation maintains a modelanalysis laboratory at Denver, and the TVA maintains one at Norris. The Corps of Engineers of the Army, charged as it is with the improvement and control of most American rivers and harbors, conducts model analyses in various laboratories, the largest of which is the U. S. Waterways Experiment Station, at Vicksburg, Mississippi. The photographs and figures accompanying this discussion relate to the latter laboratory. A further glance at its current operations will afford examples of most types of problems to which model-analyses are applicable.

Man constructs dams across rivers with various purposes m view to regulate the stream flow in the interests of navigation or flood control; to concentrate head in the interests of power development; to conserve water in the interests of irrigation Conduits and spillways frequently present perplexing problems, among which are the precautions to be taken to prevent dangerous erosion. The danger of erosion arises from the discharge at high velocities of water through conduits or over spillways. The problem is to reduce these velocities before the water reaches the soft materials of the river valley. In such case, the model-method of analysis

is easily and directly applicable. To describe by illustration, consoit two of the photographs on page 141 that have to do with a model of the spillway for the Creat Salt Plains Dam, about to be constructed on a tributary of the Arkanasa River. One of the photographs shows the high-velocity discharge onto the erodible material; the other shows the results of provisions for the "stilling" of the light velocities. Relatively speaking, the erosion has been made negligible.

IN their natural states, few rivers are susceptible of econome awayation Most of them must be "improved", that is, made deeper Their are several methics and of improving rivers for pavigation by cambration, as on the Ohio and the upper Mississippi; by increasing the critical of low water flow, as on the Mississippi when the Mississippi water flow, as on the Mississippi flow of the Mississippi chows the June 1990 of the Mississippi flow St. Louis

Description of the open-river method of improvement movless consideration of the elements of an alluvial river. Such a stream consists of long, relatively deep pools, these extending along the concave sides of the river lends. Between successive pools are short, relatively high, "crossing" har? In effect, the river is a series of flat, deep reservoirs, or pools, the water from one reservoir spilling into its downstream neighbor over the steep, shallow, crossing bar. Thus, the

situation facing the navigator is this: through perhaps 95, percent of his course he is in a channel liaving several times the depth his vessel requires; but, through the remaining 5 percent of the course he is crossing over bars where the depths very likely are less than he deares. The object of open-river regulation is to provide such training works as will cause the river to erode deeper channels over its crossing bars. In such a case the method of model-analyses folls an essencially great need.

Man attacks his flood problems in various ways. by impounding the excess waters and releasing them only when they will do little or no damage, by increasing the capacity of the river channels; by constructing levees which exclude the water from restricted areas. The small-scale model is a valuable tool. both in enabling the engineer to select the method of protection best adapted to the situation at hand, and in aiding him to develop details of design after the method has been selected. Two more of the photographs show the model reproduction of a bridge at Johnstown. one illustrating flood conditions at 12:30 A.M., March 18, 1936, while the other presents the improved channel takmg all the flood water. Business in town goes on as usual

The mafavorable deal which Nature provides in connection with its livers is repeated in connection with its harbors. The tides, the occan currents, the waves, and and the bed materials blend together to form a phenomenon which man perceives clearly only in its re-altant form. In the face of such complexity, the small-sale model is of only limited reliability, but so difficult are the problems that the and provided by a model, even of limited reliability, frequently is valuable

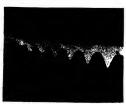

Thus, in the manner indicated by the camples cited, the profession of hydraulic engineering marches on, its progression of progress over many of its most difficult obstacles being lighted by data from small-scale model experiments. One can say the same thing in another way; which is the baffing complexity with which Nature endows flowing water has found to the complexity with which can be completed by the complexity of the complexity with which can be completed by the complexity of the same conditions of the small-scale model.

Above: Waves impinging on a model of a breakwater. Such waves as these must not enter the harbor

In the Johnstown model: a bridge past which flows the equivalent of the 1936 flood. At the left is the condition as it was and at right is shown the lower stage heights of the great flood with the improved channel

No More Blown Patterns

A SHOT-GUN shell recently announced, which will eliminate blown patterns, means much to term the short patterns and the short patterns which the short patterns with the short patterns and the short patterns and short the short patterns and short patterns and short patterns and short patterns and short patterns out of every 100, made with conventional shells, which unaccountably are much more widely scattered or "blown" than the others.

In the ordinary trap load, for example, 90 shells out of every 100 would put 60 to 80 percent of their pellets into a 30-inch circle at 40 yards. But the remaining 10 shells would all be below 60 percent And three of four of these would seater their pellets so widely that barely more than 30 percent of the shot charge would get into a 30-inch circle at 40 yards. Even with the best of gun pointing, it is obvously shere luck whether, with such a pattern, the clay target is struck by some of the

Top Wad in Shot-Gun Shell is the Villain That Causes Them . . . Elimination of Wad by a New Crimped Shell End . . . Unimpeded Shot Charge

pellets or whether it flies blithely through one of the numerous holes.

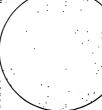

Thousands of patterns have proved that the top wad is the villam in this story. With the top wad shead of it, the shot charge rushes from the muzzle at about 1200 feet per second. The terrific resistance of the air on the flat surface of the top wad at this velocity checks it's speed and causes it to get in the way of the shot. Most of the time it slides along the outside of the shot charge or is hipped entirely out of the

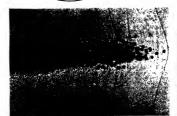

way and does little damage. But, about ten times out of every one hundred, the top wad obstructs the column of shot, and a blown pattern results. Shells with the new Remington Crimp

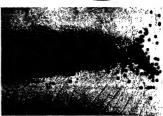

avoid this effect, because they contain no top wad to get in the way of the shot column. They have exactly the same contents as are used in ordinary-crimp loads at present. To provide means of load identification and to waterproof the shell, a waxed paper disk only three one-thousandths of an inch thick is pasted to the crimp closure. On firing, the shot charge pushes the top open and breaks the disk into six pieces These remain affixed to the shell body. Hence, from the very beginning, the shot charge is completely unobstructed in its flight toward the target, and produces a blowproof pattern.

Above: Shotsum shell at right is for reaventional type in which the top wad causes occasional blown patterns. Other three shells show steps in folding and sealing the rimp of the new shell described. Lower right: The spark photograph shows how the top wad breaks up the shot charge. resulting in a blown patter such as shown at the right. Lower the continuous shot charge coming from the new type shell. Such a charge produced pattern at left

the starting table. It has started from a standstill
under its own power. Below. A Syncro

Ace Special, less than five inches high

MINY gasoline engines with an average weight of only six ounces, a height of four inches, and a horsepower rating of one sixth are furnishing the motive power for proportionately small airplanes which have made remarkable endurance, distance, and altitude flights. The engines form the basis of a hobby which is daily attracting new recruits of all ages to the ranks of the gas-powered model-plane enthusiasts. It has been estimated that there are more than a thousand clubs in the United States in which membership is exclusively confined to those model-plane flyers whose ships are gasoline powered. Doctors, lawyers, business men; all professions and crafts are represented in the ranks. They have taken the small plane from the classification of a bov's plaything and made it the foundation of a serious pursuit which helps to pay weekly wages in hundreds of retail hobby stores, in the factories where motors are manufactured, and in shops where plane equipment and materials are produced.

The hobby offers triple fun. First is the pleasure of building the planes and

Half a Pound of Power . . . Avocation Makes Big Business . . . Inexpensive Midget Motors by Mass Production

By L. B. POPE

second the thrill of secung them fly, The flights give a sense of adventure, and many an altitude record or transoceanic hop has been made vicariously More important, though, is the very real toy of competition; flying the plane in one of the frequent inter-club or intraclub meets. Each "aviator" keeps formost in his mand the hope that his plane will someday establish an official record which will serve as a goal for the thousands of other model-plane enthusiasts throughout the country.

The reason for the recent increase in interest in gasoline powered model airplanes is not hard to find. The story is the familiar one of mass production making available a quantity of some product at a price within the means of all interested. The gasoline motors on the earliest model airplanes represented hours of careful planning and work. They were beyond the average model (an who had neither the equipment, skill, time, nor money necessary for their construction. But modern shop practice has changed the whole picture in favor of those who would fly gasolinepowered planes, but who for one reason or another cannot design and construct a suitable engine.

THE modern little power plants that are constantly setting new model records are carefully engineered working miniatures of those two-cycle gasoline engines commonly used for outboard motors, small water pumps, power lawn mowers, and so on. There are many manufacturers who offer a variety of designs and hence there is a wide price range from which to select. Partially assembled engine kits, requiring only a screw-driver for complete assembly, at about \$5 is the minimum. Complete motors with batteries, coil, tank, and accessories are priced up to \$22. The motors are rated at from 1/7 to 1/2 horsepower although they are only three or four inches high and weigh but a fraction of a pound when unstalled. To arrive at a clearer idea of what a model-plane motor really is. 16 typical camples were selected and their characteristics averaged. The results give a hypothetical motor weighing six ounces, slightly less than four mehies high, with a horsepower rating of 1/6 at 8000 revolutions per minute. The hore and stroke are each 3/4 inch. (Of the motors used to obtain these average figures only five had equal stroke and bore dimensions.) It would cost \$13.64 to buy this imaginary composite motor.

cost of the model power plant, ready to

be put into a plane and run

Since this composite and average motor is only four inches high, the component parts are tiny indeed, yet standard machine shop practice is followed in the manufacture of all the various small parts. Most of the crankcases are die cast. Cylinders and pistons are usually machined from the solid, then hardened, ground, and lapped to fit. The pistons are smooth wall or with one or two piston rings Connecting rods may be die cast or steel drop forgings. with hardened and lapped bearing surfaces The crankshaft, drop forged or machined, has usually only one solid bearing area. (Some manufacturers advertise ball bearings at slight additional cost.) At one end of the crankshaft is the connecting rod and the counter-balanced crank; the propellor is on the hub at the other end. Between the two is the bearing, an inch or two long, of bronze or steel. A balanced flywheel, grooved for rope starting, is sometimes used on the 1/5- and 1/4horsepower motors.

A glance through the advertising literature of model engines will reveal such phrases as chrome-molybdenum crankshaft; tool-steel crankshaft; cadmium-plated head; aluminum piston; micrometer needle valve; bronze bearings; transparent gas tank; or perhaps

the maker will stress the fact that his particular model may be run either upright or inverted, a fact which might influence the model builder who has ideas for motor cowling. Thus does competition in this field, as in many other sumer. In order to attract the public, each manufacturer constantly strives to improve his product.

The fuel system of these model-plane motors includes a gas tank, a needle valve, and an intake manifold. The tank may be of metal or some transparent material and is supported in back of or under the cylinder. It holds only a few ounces, as very little gas is required for the motors. The fuel is usually a mixture of gasoline and motor oil (S. A. E. No. 70) in the proportion of four parts to one. The fuel passes by suction through the needle valve and into the crankcase, where the oil luhricates the main bearing and other moving parts, and then into the combustion chamber where it is burned.

The electrical circuit of the motor includes batteries, coil, condenser, contact points, and a spark plug. Small flashlight dry cells are used to supply the necessary three volts. The coil and condenser together weigh only two or three ounces and furnish the hot spark which ignites the gas. The contact points are on the driveshaft directly behind the propeller and make contact once every icvolution Spark advance or retard, as may be necessary for proper operation of the motor, is accomplished by moving a lever located behind the hub. The lever shifts the ignition points forward or backward to make earlier or later contact. The spark plugs are made by several manufacturers, but are of standard sizes about one inch high and with 3/8-24 or 1/4-32 threads.

The planes which carry and are powered by these small engines usually are the results of hours of labor on the

At the right, an Ohleson motor showing how the coil and con denser are connected Below. A Syncro motor with the gas tank as part of the streamlined crankcase assembly. Below, right: The baby Cyclone motor has a remote control throttle and a rotary intake valve

part of the owner. They may be bought complete or in construction kits, but frequently they are the embodiment of the hobbyist's own ideas and the result of much personal experience.

With many different sizes and shapes of gasoline-powered model planes, some sort of regulations must exist in order to run competitions on a fair basis. Thus the National Aeronautic Association, Model Division, has established contest classifications, and rules governing them, for all model planes including gas—powered types.

The models are classified according to the area of their supporting surfaces, most

supporting surfaces, most gas-powered models are in "E" class with an area of more than 300 square mohes. All regulations are kept in mind while the plane is building, otherwise it will not be licensed and qualified for officially sanctioned meets. There are regulations governing minimum an examinum weight, cross-sectional area of fuselages, and wheel size. The landing gear must be demonstrated to be strong enough to support the plane when gliding to a landing from a height of four fret, without damage and without noung over

THE serious and adult nature of the hobby is shown by the official classification of contestants. No one under 16 years of age may compete without special permission and supervision. Records made by model planes are not

Photograph by Jacob Deschin

Details of plane construction. The large dry
cells shown on the ground serve merely as an
engine starting aid and are detached before flight

official until they have been accepted by the Contest Board of the National Aeronautic Association. Official recognition is given to duration records only. All official records must be made in sanctioned meets or under specific direction of the Contest Board of the N. A. A New records must exceed the old ones by 2 percent in order to qualify for recognition.

Official contest flights are made by allowing an engine run of 20 seconds. the time being limited by either a mechanical flight timer or by fuel measurements. In that time the plane must take off from a standstill and climb as far as possible. After the motor stops, the plane glides to the ground. The flight duration is timed from the instant the wheels leave the ground or starting table until they hit the ground. An indication of what these little planes can do is the winning time of a recent meet. First place was won by a flight lasting 20 minutes and 20 seconds. This means that the plane was so nicely trimmed that it soared in the air without any power for exactly twenty minutes Other non-competitive and non-official flights without the 20-second motor run limitation have been made which lasted more than two and a half hours. A welldesigned gas-powered model plane may cover 50 airline miles and soar to a height of more than 10,000 feet.

The surest way to antiagonize any devotee of this universal hobby is to refer to his ship as a 'top plane,' for they cannot truthfully be called toys in any sense of the word. The gas-powered model plane enthusiasts are a hard working and serious let.

A For those readers who want to obtain more specific information on this interessing hobby, and further details of planes, motors, and equipment, a list of manufacturers and dealers will be sent on request. Please enclose a stamped envelope.—The Editor.

A Remarkable Triple Star

VERYONE knows that hundreds of double stars have been detected by the spectroscope. As the stars move in their orbits, they sometimes approach us, and again recede, and the positions of their spectral lines shift accordingly. By following these changes, we can find the period of revolution in the orbit; but to work out its size is not so easy. If the orbit is turned edgewise toward us, the motion at certain points will be directed straight toward the Earth or away from it, and the spectroscopic observations will reveal the true speed. But if the orbit is tilted at some other angle, there will be no point on it at which the motion is in our direct line. Even at best, a large part of it will be sidewise, and only a fraction (in technical phrase, a component) of the velocity will be in the right direction to shift the spectral lines. In the extreme case when the orbit-plane was squarely at right angles to our line of view, there would be no change in the distance, and no Doppler effect, however rapid the actual motion.

It follows that spectroscopic observations can give us only minimum values for the real speed, and the real size of the orbit But this is not all, the two stars of the pair, as Newton showed long ago, will move a Newton showed long gravity, keeping on opposite sides of it, in m orbits of the same shape, but different sizes. The more massive star will have the smaller orbit, and move slower.

With two stars of about the same brightness, both spectra will be visible on the plates—one shifted to the red when the other is deplaced to the volet —so that the dark lines appear double, and considerably "washed out" by the superposition of the continuous spectrum of the other star. In such a case we can find the distance of each star from the center of gravity and their distance from one another—still subject to an inknown correction for the orbital inclination.

It is only when the two stars eclipses one another that all uncertainty can be removed. In this case the melination can be removed to the stars, the start of the stars, he had been also their next all diameters and their masses. There are about 30 yeatems for which this full information is available. Almost all these stars are larger and brighter than the Sun—for the fairly obvours reason that bright stars can be seen at great distances, and have an our observing lists than those which shine (cebly.

How the Spectroscope, Working on a Star Whose Secrets the Telescope Does not Reveal, Affords a Striking Abundance of Detailed Facts

By HENRY NORRIS RUSSELL, Ph.D.

Chairman of the Department of Astronomy and Director of the Observatory at Princeton University Research Associate of the Moun

They are mostly hot white stars too and again the reason is intelligible. A white star gives out a great deal of light per square mile. If it has a fainter companion of different color and temperature, this will be redder, and have a lower surface brightness, so that, though fainter, it may be as large in diameter. or even larger than its primary. This obviously sets the stage for a conspicuous eclipse, if only the inclination of the orbit is favorable. But if a bright red star has a fainter white companion, the latter will be of very much smaller diameter. If it comes in front of its big associate, it will obscure so small a part of its light that the change is most unlikely to be detected; and when it goes behind, only its own light a small percentage of the total for the pair-is cut off. Hence, even if eclipses occur, they are likely to escape observation, unless conditions are unusually favorable. The remarkable system Zeta Aurigae, in which the big red star is more than 20 times the diameter of its white companion, is one of these exceptional cases

DUT if there is a pair of stars of other benearly equal size and brightness, the chance that they will eclipse one another depends only on the orbita being nearly edgewise to us, and it should make no difference whether the stars are white or red. We actually find many such pairs of white stars, and plenty of yellow and reddish ones too—but the latter are all dwarf stars of about the size and brightness of the Sun, or smaller.

smaller.

But eclipsing pairs in which both components are guant stars of low density are very rare. This suggests that it must be decidedly unusual to find a double star composed of two red or yellow guants, and among the far wider pairs, which are resolvable with the telescope, this is the case. Occasionally we find a pair, such as Camma Leonis, in which the two are of about the same brightness and color. But the great majority of doubles among the giant stars have companions much fainter than themselves.

and usually "earlier" in spectral type and whiter in color.

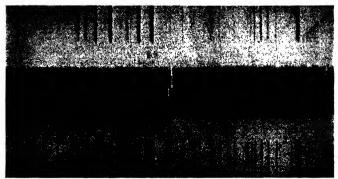

The same thing is found among spectroscope binaries. There are very few giant stars which show double lines, and have companions similar to themselves. Capella is a conspicuous exception, but a rare one. Usually only one spectrum can be seen and we are left with no way of estimating the real size of the orbit or the masses of the stars. Once in a while, luck flavors us.

For example, the third-magnitude star Beta Capricorn—which has a spectrum of Class G, like Capelle—was found by Campbell in 1899 to show changes in radial velocity, which later proved to have a period of 1375 days, or 33 years. Only one spectrum was visible. An orbit was calculated, showing that the distance of the bright star from the center of gravity of the system was 2½ times the Earth's distance from the Sun (plus the allowance for the unknown inclination) and the star was tactily placed on the list of those about which we had found out all we could all we could all we could all we could be a spectrum.

But, in 1935, three new spectra were taken by Sanford at Mt. Wilson on successive nights. These extended farther to the violet than the earlier plates, and showed the great H and K lines of calcium.

Layten, to whom the plates had been sent, noticed a remarkable thing. The H and K lines in a G-type star are normally very wide and diffuse and very strong. In this star they were weak and shallow, with narrow, fairly sharp lines in the middle. What is more, the sharp H and K lines slowed a conspicuous displacement in two days, compared with the numerous lines of the main spectrum.

Sanford then began to observe the star steadily and soon found that these calcium lines shifted periodically in a period of between eight and nine days, it was now evident that this is a triple system. The new lines belong to the fainter component of the system of four year's period, which is itself double, with a period of 8.678 days. It is a much

Courtest The Autrophysical Journal
Two spectrograms of Beta Capricorni (the two-part central area of the illustration) taken two days apart and adjusted for
coincidence of line detail of star A. Strong K lines of calcium seen at the center of the half-one belong to star B and are
definitely out of step. The present semi-popular arcount is hased on the paper by Sanford, published in The Astrophysical
Journal, Volume 89, No. 3. In that journal the American professional astronomer publishes the official accounts of his
researches but, since these are written for the scientist, they often are abstrace and Professor Resuled explains them here

fainter than the principal star that its lines would be completely masked by the stronget spectrum of the latter, were it not that those two lines fall in the middle of great wide dark lines in the other spectrum, which afford a "window" through which they can be observed. Three silteon lines belonging to the fainter star (B) and showing corresponding changes in velocity have also been detected in a "window" formed by the strong cyanogen band in the G-type spectrum of star A.

The strength of these lines of sonized when, and the narrowness of the calcium lines, show that star B must be much hotter than the first—of Class Bis—like Algol. A spectrum extending to 3200 in the ultra-worlet shows that, in this region, the light of star B is considerably stronger, in comparison with that of star A. Thus is as might be expected.

No lines belonging to the third body C have been detected. It must be considerably fainter than the second.

If this interpretation is correct, the velocity of the center of gravity of the close pair, BC, should show changes in the four-year period, always opposite in direction to those of star A, so that when plotted they should show a curve of the same shape, but upside down. Sanford's observations have now been continued over almost a whole period and they show conclusively that this is the case The proof that we have here a triple system is thus completed.

The observations of the wide pair now cover 40 years, and make it possible to

find an accurate period, 1374 days. The orbit has a considerable eccentricity (0.42). The minimum value for the distance of star A from the center of gravity (on the assumption that we see the orbit edgewise) is 395,000,000 kilonieters or 2.65 times the Earth's distance from the Sun. The pair B + C is on the other side, at a distance of 360,000,000 kilonieters (241 astronomical units) The size of the relative orbit comes out therefore nearly that of Inputer's orbit about the Sun. As the period is only one third of Jupiter's, the masses must be much greater than the Sun's. They come out 4.35 times the Sun for star A, and 4.77 for B and C combined

(If the mclusation of the orbit plane is t, the distance given above must be multiplied by cosec t and the masses by cosec t. For example, if $t = 60^\circ$, the distance of the star comes out 60 astronomical units and the masses 67 and 7.3 times the Sun's.)

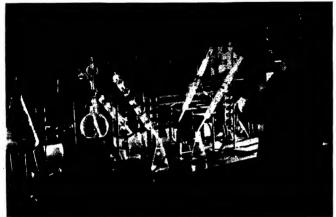

The orbit of B about the center of the pair BC is moderately eccentric (e=0.36 but is small, with a radius of 4,200,000 km. if it is seen edgewise) It can be shown from this that star C is, in all urobability of small mass.

Working, as an illustration, on the assumption that the inclination of the larger orbit is 90°, we have the combined mass of BC 4.77 times the Sun's. For this mass, and a period of 8.68 days, the distance of the components can be calculated and comes out 21,200,000 km. If the inclination in the small orbit is taken to be 90°. C is found to be 17,000.

times as far away as B, so that the mass of B is 40.5 times that of C, which makes of B is 4.05 times that of C, which makes the masses 3.93 and 0.95 times the Sun's. With different assumptions regarding the melinations, different tesults would be reached; but, unless we assume that the orbit of the wide pair is seen almost edgewise, and that of the close pair at a small angle, the mass of C always comes out small compared with B.

T-BHS accounts for the failure of its keyertum to appear, for by the well-known relation the luminosity of a star varies about as the cube of its mass (Recent work midicates that the 3.3 power is a better approximation.) On this basis, if B is four times as massive as C, it should be a hundred times as breight

Comparing A and B, on the assumption already made, we find that the latter has a mass 90 percent as great and should give 70 percent as much light. It appears to be considerably fainter than this; but a moderate and wholly permissible alternative in our assumption about the inclinations of the two orbits would lead to complete accordance The only hope of clearing up this uncertainty lies in the possibility that one or other orbit is so nearly edgewise that eclipses occur For AB this would demand an inclination so very near to 90° as to be highly improbable; for BC the chances are rather better, but the light of A would drown out the variation so that very precise observations would be needed .- - Princeton University Observatory, June 14, 1939.

Equipment for chlorophyll and vitamin research in a biochemical laboratory

Secrets of Life's Colors

COLORS are clues to life's most fascmating mysteries. Green, red, and yellow—the most meaning-ful life-colors—are guiding scientists through regions in which Nature, by the changing beauty of light waves, signals the locations of treasure caches.

Many of these treasures are turning out to have immediate cash value. Many are discoveries which promise other stores of knowledge that will stimulate civilized progress and some day will alter the modes of man's existence.

Plant green, the pigment chlorophyll, seems to be leading man toward great manufacturing secrets and the ultimate production of both fuels and raw materials as well as foods in almost unlimited quantities. Experiments are beginning to teach man the mechanisms of energy use and fuel production in green plants. Many of the details are already known. When many more are known, then foods, raw materials, and fuels will be almost as cheap as air and water and sunlight. Even now, chlorophyll has practical value. In this country each year thousands of pounds, extracted from leaves, are used to color foods, soaps, Chlorophyll, Key Substance of Life, Mysteriously Concentrates and Stores the Sun's Energy... Gives Promise of Vast Resources to Industry

By BARCLAY MOON NEWMAN

and candles. To medical science, chlorophyll is of inestimable, immediate significance. The architecture of its big molecules is amazingly similar to the architecture of the molecule that runs red in blood.

Green, the prime pigment of the plant world, is most intimately related to red, and a superior of the plant world, is most intimately related to red, and a superior of the plant pl

animal red are abnormal and puzzling. Yellow is as widespread and as important as green, though masked by the chlorophyll of vegetation. A light filter which absorbs most of the green rays from chlorophyll but permits the passage of other light has been devised by the Eastman Kodak Company. A green field or a green forest observed through this filter is a fiery yellow admixed with orange and some slight red. For in every green plant cell there are yellows and yellow tinged with orange and red. When aviators, intent on dropping bombs, observe the landscape through this special light filter, the green of vegetation looks fiery vellow-but the green paint of camouflage still is green,

and there is no yellow. Because of this

difference between greens-a subtle dif-

ference made evident by the filter—and because of the presence of hidden yellow in the one case and not in the other, the bombers know where to loose their destruction. This application of pure science is practical—and of immediate value—if you call war practical and bombing valuable.

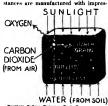

Definitely practical and definitely of inestimably great immediate value are science's new facts concerning these yellow pigments. For, chief among plant vellows are the carotenoids-source of the millions of dollars annually spent to obtain vitamin A, the essential nutrient derived from carotenoids. And who can put a price on the vitality and health that medical science has brought us through its increasing understanding of carotenoids and vitamin A? Certain internationally famed experts, besides, are convinced that vitamin A is one factor in the problem of lengthening the span of human life.

The value of carotenoids to the plant still unknown, but their occurrence is related to rapid growth and high activity, as in the green leaf, where photosynthesis is under way. Green chlorophyll is never found unaccompanied by these mysterious compounds. Probably their secrets are bound up with the problem of photosynthesis—where chlorophyll has a role of predominant significance.

Green is spread extensively over the earth. This abundance is a sign that the greenness of the chief plant piguoni, chlorophyll, is indispensable to practically every form of life on this planet. Chlorophyll is an indispensable promoter of the transmutation of solar energy into the energy of life activities. Without it, there would be no food, no coal, no oil, and no men. An enlightening and fascinating quiz is to ask a succession of questions tracing back to the origin—the Sun—the energy in the various prominent items of our dietary, fuel, and raw material economies.

PHOTOSYNTHESIS—the synthesis in plants of sugars and other nutrients by the use of sunlight, is almost uniquely interesting as a chemical problem-and almost uniquely complex, too. In this process, the living tissue of the plant absorbs molecules of water from the soil or perhaps a watery habitat. Rays of light energy plunge in from the Sun. The plant uses green chlorophyll to deal with these rays. That is, chlorophyll somehow manages to concentrate their energy and to store it-probably by stimulating the reaction of water molecule with carbon dioxide molecule. The reaction of these molecules results in the formation of sugar and starch, which are energy-rich molecules. Oxygen is a by-product poured out into the air and later becomes the very breath of every creature. If it were not for photosynthesis, the quantity of oxygen in air would gradually diminish and, so runs the evidence, life would vanish almost entirely.

After photosynthesis, by intricate steps sugar is made to yield a van list of maternals needed by life. Thus, from sugar, by fermentation in the plant cells, alcohol is made, and afterward participates vitally in the chemical reactions whose sum is life. Sugar likewise is the raw maternal for making glycerine, oils, fats, proteins, vitamins, pyments green, red, and yellow. All these substances are manufactured with impres-

Courtesy College Entrance Book Co The green plant cell takes in carbon dioxide and water and, with the aid of chlorophyll (in tiny chloroplast bodies) combines them to make sugar and starch. By-product: oxygen

sive efficiency out of the prime product of photosynthesis: sugar, whose energy came from the Sun and whose atoms once were water and gaseous carbon dioxide. Photosynthesis is the world's most efficient process.

Investigation shows that there are, in fact, two green, having very nearly the same art hitecture of molecule: chloro-phyll a and chlorophyll b. When extracted and crystallized, a is blue black; in alcoholic solution it is greenish blue. The solid crystal of b is green black; it dissolves in alcohol to a beautiful pure green. Readily a is changed into b by delicately taking away two atoms of hydrogen and replacing them with an atom of oxygen. The life scientist motes that they are always together in any green plant cell; each is an essential cog in the machinery of photosynthesis.

Each chlorophyll molecule is a web of carbon, hydrogen, oxygen, and nitrogen atoms, with an atom of the metal, magnesium, as a centerpiece and chief feature, when the molecule is taking part in photosynthesis.

The red hematin structure is also a web of carbon, hydrogen, oxygen, and nitrogen atoms, but with an atom of the metal iron as a centerpiece and chief feature, when the molecule is taking part in the transport of oxygen in living things.

To ferry oxygen is the destiny of the hematin architecture. That it makes blood red is a mere happy signal of Nature—not always so eager to help man by arresting signals. The disk-like blood corpusele is red because its activity is the transport of oxygen, and this activity calls for hemoglohm—a giant globm, or protein, to which four molecules of hematin are, butched

The pallor of anemia is another signal, this time of warning, that the body needs more iron in its blood, iron in the form of hematin.

Where oxygen is plentiful, as in the lungs, hemoglobin forms a loose combination with it. Where oxygen is low in concentration, as in the tissues deep within the body, the oxygen atoms break away from the lemoglobin and are absorbed into the tiny laboratories of the cells. There the oxygen is used to burn, to react with, the fuels and release their energy for running the mechanisms of life. These fuels were formed originally in the plant, by the aid of green chlorophyll in photosynthesis, and originally their energy was sublight. All fiesh is grass, which labors in the sun.

THE iron atom, central feature of the lienatin molecule, as empowered to attract a molecule of oxygen—two atoms and seize it, holding it in the web until the appropriate time of release. Thus the huge henoigholin molecule, having four hematin structures attached, can hold four molecules of oxygen at a time. Each red corpuscle, having many hemogloin gaints within its delicate fabric, can carry many oxygen atoms. The transportation of oxygen to the hungry cells fair from the lungs as therefore an effect at the contract of
No seventist thinks that the close likeness of hematin and chlorophyll is an accident One ancient day, when earthlike was young and low in type, live substance realized the possibility of exchanging an atom of iron for one magnesium in a web like that of green chlorophyll. Oxygen-ferrying was facilitated. Red blood, and its possessor, the higher animal, could later appear on earth.

New discoveries yield striking evidence favoring this theory. Man cannot exist without minute quantities of copper and manganese in his system. These metallic elements, it has recently been found, promote the formation of hemoglobin in factories located in hone marrow. And lately, too, it has been found that chlorophyll formation does not take place in the leaf in the absence of minute quantities of copper and manganese.

Now color leads us—as it did the investigators of the mystery of life—to one of the major discoveries of science. Throughout all matter that is alive, hematin is found—in the bacterium, in the towering redwood tree, in the aquatic animalcule ameba, in man.

Why, then, is not all living material red? The hematin is present in too low

a concentration to cause any color to show up

Nevertheless, the high sensitivity of the spectroscope sorts that light waves made to pass through live matter and invariably finds those wavelengths which tell that hematin is definitely there, though in proportions almost infinitesimal. Still, distributed however thinly through vital substance, the hematin molecules-we now know--make possible a vastly complex mechanism of energy use. The hematin web is continually busy taking oxygen from this molecule or that, and ferrying the oxygen to other molecules-which then react, usually by uniting with the oxygen, and so are oxidized, burned to release heat or other varieties of energy.

Thus, one great mystery of life is slowly beginning to give up some of its treasures. Oxidation and energy transformations at moderate temperatures constitute a secret not only universal in living things but also thrilling in promise to man. Cold, white light like that of the firely and deep-sea monster will be soft illumination in man's buildings when he solves more problems of the most efficient conomy in the world—the physico-chemical economy of animate machinery, which with automiding ease stores energy in photosynthesis or re-leases it in physiological oxidation.

SOMEWHERE in the rise of animals, protoplasm learned to put copper in the place earlier occupied by room in the hematin web, and thus made a blue from a red. The oxygen ferries—that is, the respiratory pigments—of the blood of the octopus, the oyster, and the lobster are hemocyanins and not hemoglobins. They are blue, not red.

Other lines of animal evolution used the red hematin to make their blood pigments and so were able to go lingher in the scale of life. Hemoglobin is four times as efficient a carrier of oxygen as hemocyanin, and is one of the factors in the creation of man out of lower mechanisms. Yet to this day, copper is somehow bound up in the making of hemoglobin.

Yellows outstandingly important to life are perhaps most readily seen in the carrot—from which these pigments were first solated, and so called carorenoids. They are vital to the plant and to man—and were the sole source of vitanin A until the eminent biochemist Kuhn recently taught chemists how to make this vitanin in the test tube.

In 1831, ruby-red crystals were extracted from carrot root, and named "carotin." This pigment is now recognized as a mature of at least three closely related chemical structures: alphas, beta, and gamma-caroten. In solution, the red changes to the yellow typical of dissolved or suspended molecules of carotene—as in a number of yellow flowers, in the volk of the egg, in the yellow leaf. But not all plant yellow is carotenoid; not all carotenoids are yellow.

A carotenoid is a special chemical structure a ring of carbon and hydrogen atoms attached to a chain of carbon and hydrogen atoms attached to a chain of carbon and hydrogen atoms. The ring is known as the beta-lonnoid ring, and holds many a recent Chemists first knew it as an essential portion of many a fragrant molecule, such as those many a fragrant molecule, such as those mind of wolets. They are surprised to learn that it is a vital part of the structure of vitamin A.

Science Service photo President James B. Conant, of Harvard (right), internationally known investigator of chlorophyll. (At the left. Dr. Harvey Cushing, surgeon)

The length of the chain, and the manner in which its atoms are linked, have much to do with the color. Yellow is predominant among these substances, but slight changes in the positions inkages—of the atoms and an increase in the length of the chain yield orange, red, and then even reddish violet and very rarely dark blue. The red of tomatices and of waternelons is, for example, a carotenoid—kin of the yellow of yellow to the color of green-masked yellow of all leaves. Vitamin A, however, is colorless—no one knows why.

In the backboned annual, any one of the three earontees can act as the forerunner of vitamin A. The liver accums to the three tearners of vitamin A. The liver accums to the same of this transformation of yellow mote colorless on parents with the vertebrate can set no parents which the vertebrate can set no parents which the vitamin A. The vitamin of yellow the vitamin A. The vitamin of the vitamin A. Causes however of relationship of the vitamin A. Causes however of relationship of the vitamin and mucous membranes, poor vision of dim light, weak dry eyes, and ultimate blundroses.

Eggs and milk have vitamin A derived from the animal's ration of plant yellow, or perhaps of cod-liver oil (added to the feed). The cod eats lesser aquatic life, which in turn lives directly or indirectly on sea vegetation which has both green for energy storage and yellow for vitamin A. How intricately woven is the web of life! Blo-science, medicine, chemistry, and eventually even physics (through the study of color's origins) will all amazingly benefit from present and future investigations of yellow, so closely tied up with green and the wellbenz of men with red blood.

The common yellows of fruits, vegetables, and flowers are carotenoids, but there are other yellows. A yellow scarcely yesterday discovered present in practically all living tissues, plant or animal, is vitamin G, or riboflavin, most readily obtained from nulk, a rich source and, in fact, until recently the sole commercial source. What rôle this vitanin plays in extending the life span of man is unknown, but the mouse and the rat definitely live longer when plentifully supplied with the untrient. Until recently, riboflavin obtained by a laborious process from milk was selling at many dollars per gram -- and there are 454 grams to the pound. Thus important did biochemists and medical scientists regard the vitamin. Now, thanks to improved production facilities and commercial synthesis, the price has been much reduced.

THIS yellow takes us back to red. Like hematin, riboflavin is essential to the release and transfer of energy within the vast systems of the life mate rial. It is beginning to appear that in this yellow we have a link between the vitamins and the enzymes, which are the stimulators and accelerators of chemical activities within a living thing. Riboflavin, attached to certain huge protein architectures, endows them with the power to step up the rate of burning and energy- and atom-enchange in many vital chemical reactions. Hence riboflavin, the yellow, is a companion of and co-laborer with hematin, the red, in the control of life's breakdown of fuels.

The world of life is a world of color.

And the ho-investigator is finding profound meaning in the play of color.

The human eye that looks out over this
world is struck by a myriad of clues to
Nature's deepest and most significant
secrets. And the very eye sees by grace
of the pigments that signal so fascinatingly.

Vatamin A, born of yellow, is a partial of the mechanism of the human retina, the light-sensitive photographic film, as well as a part of visual purple and other evisual pigments known to exist, but still jump mysteriously, in the eye's photosensitive will be mysteriously, in the eye's photosensitive film. The red which vitalizes the brain and nerves and eye is the offsyring of only living mechanism of man, yellow and horized are specifig the use of the energy which green following the properties of the energy and which green following the distribution of man, yellow and which green following the distribution of the energy and which green following the distribution of the energy and the summer. Scientists find much profit in such thouse the sentence of the

WHAT SIX YEARS DID

In the Design of Large X-ray Equipment, Progress Has been Extremely Great in the Past Few Years... Hospital X-ray equals \$90,000,000 Worth of Radium

A MILLION-VOLT X-ray outfit to small that it can be housed in existing hespital buildings, yet so powerful that it gives X-raduation equivalent os everal thousand grams of radium, has been built by the General Electric Company for the Memorial Hospital in New York, where research in the treatment of cancer is being carrier don. It is estimated that the radiation from it, based on present-day radium costs of \$25,000 per gram, will be equal to \$900,0000 worth of radium.

The new tool of medical research was built following a long period of study with the objectives of reducing the size and cost of very high voltage X-ray equipment, thus increasing its availabili ty to hospitals. The new apparatus can be produced and installed for far less cost, for example, than the well-known 800,000-volt units of 1933 which required a special building to house them and their vast array of supporting and contributing equipment. The 800,000-volt unit needed a building 62 feet long, 32 feet wide, and 36 feet high, and many tons of lead to protect operators and patients from the cumulative effects of X ravs.

The new equipment consists of a transformer of novel and radical design, together with an X-ray tube built of 11 sections. Transformer and tube are consistent of the consistency of two sections bolted together. The total weight, including 1000 pounds of lead for X-ray protection, is 4000 pounds.

Revealing the filament end of the tube and part of control mechanism

The outside steel shield (left) that encloses the tube and coils

Lowering the 100-coil transformer over the tall and slender X-ray tube

The transformer operates on threphase, 60-cycle power, and is designed to produce 1,000,000 volts peak at three milliamperes or more The tube is mounted vertically within the transformer in the space normally occupied by an uru occer. It is three and one half inches in diameter and 56 inches long The glass portion is completely shulded, electrostatically, for its entire length by the surrounding transformer.

The high tension winding of the transformer consists of more than 100 thin, flat coils of wire, built like huge pancakes with holes in their centers. These cakes with holes in their centers. These center passes the X-ray tube with the target end at the bottom and grounded, and the lot cathade filament at the top Completely enclosing the tube and couls is a steel shaded which, in effect, becomes the core of the transformer, although it so no the outside of the coils.

ANOTHER unusual feature of the equipment is that gas is employed as an insulating medium instead of the conventional oil. If oil were used in this unit, about 12,000 pounds would be needed, but only 100 pounds of gas (di-chlorodifluoromethane) perform the insulating function

There are no moving parts. The control of the unit is entirely electrical, and the enclosure of the million-volt circuit in a grounded metal tank eliminates the hazard of electrical shock.

Applications outside the medical field include its use in industry, such as for radiographic examination of large steel castings five inches and more in thickness.

Why the Earth's Magnetism?

MAN has known that the earth is a huge magnet almost as long as he has known anything about magnets. However, scientists have labored and speculated in vain for over 300 years since that discovery in the attempt to find a reason for its magnetism. Systematic and careful experiments have been made on a scale almost greater than any other scientific project. Special non-magnetic wooden ships have sailed the oceans charting the lines of force. Explorers have carried delicate instruments with them to out-of-the-way places to make careful magnetic meas-

DECL INATION 1920 1540 1800 1700 Figure 1. Secular variations of the earth's magnetism, as observed at London since 1540

urements. Numerous stations scattered over the earth's surface have watched

the hourly, daily, and yearly fluctuations for many years with extraordinary patience and precision

In the light of this extensive experi mental work, a recent paper in the Physical Review, official publication of the American Physical Society, will cause great interest among scientists the world over. This paper, entitled, "On the Origin of the Earth's Magnetic Field," by Dr. Walter M. Elsasser of the California Institute of Technology, has cast new light on this old problem and possibly pointed the way toward its ultimate solution

Early theories of the earth's magnetism were based on the assumption that the earth is a huge, permanently magnetized body Such theories would no doubt be very successful if it were not for one serious obstacle. The interior of the earth is very hot, being at least several thousand degrees centigrade, and all permanently magnetized bodies lose their magnetism when they become hot. The only alternative, then, is to say that the earth is a huge electromagnet, not a permanent magnet, and that the magnet-

The New Elsasser Theory . . . Radioactivity Heats Earth's Interior, Heat Sets up Eddies, Currents of Thermoelectricity Flow, Causing Magnetism

By C. W. SHEPPARD

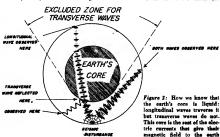

ism is caused by enormous electric currents. These are estimated to be in the neighborhood of a billion amperes. Measurements of the distribution of the lines of force over the earth's surface show that all but a few percent of these cur-

rents must flow in the earth's interior. The remainder can be accounted for by a ring of charged particles flowing around the earth somewhere between the stratosphere and the Moon. A fluctuation of the earth's magnetism in step with the 11-year period of the sunspot activity can be traced to this ring, whose charge dies slowly away only to be replenished by particles thrown from the Sun by the violent cruptions on its surface during the sunspot maxımıım

Although a description of the fluctuations of the earth's magnetism would fill many pages, its most important variations, from a theoretical standpoint, are the long-term, or secular, variations. Not only does the earth's magnetism change gradually over a few centuries under these variations, but also the north and south magnetic poles move around slowly (Figure 1). Any satisfactory theory of the carth's magnetism

must give a proper explanation of this phenomenon. The fact which makes scientists scratch their heads the hardest, however, is that, although the earth's magnetic poles are near the north and south geographic poles, they do not coincide exactly with these geographic poles. What can be the forces at work which make the earth's magnetism tend to be parallel with its axis of rotation and still allow it to deviate a small amount?

ALTHOUGH our information as to the nature of the carth's interior is somewhat meager, there are good reasons to believe that it is metallic. The most important information on the earth's interior is obtained from the behavior of earthquake waves. These waves are of two kinds, longitudinal and transverse. The longitudinal waves vibrate in the same direction as that in which they travel. Sound waves belong to this class. Transverse waves are those which vibrate in a direction at right angles to that in which they move. The waves one obtains on shaking the end of a rope are transverse. It is well known that liquids will not transmit transverse waves. Observations with seismographs at great distances from earthquake centers show that there is a large core in the center of the earth (its

boundary about 1950 miles below the surface) that does not transmit these transverse waves (Figure 2). Therefore, one can conceive of the earth as a large ball of molten metal with a thick crust of solid material floating on top just as alag floats on the surface of a melting too. It is in this easily conducting core that the electrical currents which keep the earth meantized must flow.

Attempts to explain this current as being due to galvanic effects such as produce the electrical energy in batteries have been unsuccessful, for the currents which could be produced in this way would be much too small Elsasser's theory finds a much better explanation in thermoelectric currents. Whenever two metals are joined together, there is a tendency for a current to flow from one to the other This tendency is propor tional to the temperature of the junction and depends on two quantities called the thermoelectric constants of the metals. Unfortunately, it is impossible to measure a current without making a closed circuit. Therefore, one must have at least two junctions Then, however, the tendency for currents to flow at one junction is just balanced by the reverse tendency at the other But, if the temperatures of the junctions are different the effects no longer neutralize and a current flows (Figure 3, top). This principle is used in thermocouples, which have a wide application in measuring high temperatures and in thermostatic control Suppose now that, instead of two strips of the two different metals, we take a large number of strips and join them

Figure 3: At the right is a thermoelectric pair. Below is a per-tion of a thermoelectric chain electric chain HOT JUNCTION COPER JUNCTIONS COPPER CURRENT COPPER JUNCTIONS ROON FROM

in a closed chain so that the two different kinds of metal with their different thermoelectric constants alternate (Figure 3, bottom). Now, if we keep alternate junctions at two different temperatures throughout the circuit, a current will flow in the same way as before where we had only two strips, but a larger one. If such a situation, or something nearly analogous, could arrise within the earth, a

large thermoelectric current would flow.

To cause such a systematic alternation of temperatures, the new theory supposes a source of heat at the center of the earth. Given such a source, a turbulent, boiling-up motion would occur. The velocity of the longitudinal waves trans-

mitted by the earth's core, with other information, shows that the interior is very plastic, being somewhat less viscous than ordinary pitch. Thus this boiling motion will be fairly rapid. For the necessary source of heat, small amounts of radioactive material in the earth's interior would be sufficient. This turbulence, or convection as it is called, is the same thing as can be seen in the air above a heater or in a saucepan on the stove This convection will break up into eddies which rotate about an axis pointing radially outward from the center, and the average motion will be in the direction of this axis. Thus at the centers of these eddies large quantities of hot material will be brought up from the interior and cause temperature variations. If then these temperature variations are coupled

with variations in the thermoelectric constants of the surrounding material, a resulting thermoelectric current will be set up.

The question as to how the thermo-

electric constants will change is hard to answer. The interior of the earth is at a pres sure of at least 10,000,000 pounds per square inch. The highest pressures obtained in the laboratory so far have been only one tenth of this and little hope exists that one can go higher, for the best materials available flow like wax under the stress. However, it is known that high pressure causes changes in the crystalline structure and in the relative composition of various components of alloys, and that these changes occur much more frequently than at low pressures. Since it 18 quite certain that the interior

of the earth is made up of several different metals, a large number of these changes may occur, and thus the thermoelectric constant will vary.

However, as it stands, the thermoelectric currents merely cancel out, as there has thus far been no determining factor as to whether they will go from east to west or vice versa. This is where the earth's rotation enters. Suppose a person sits on a piano stool and holds a weight in either hand at arm's length. If he is now set into motion, he will rotate slowly unless he draws the weights in, in which case, he will speed up Figure skaters make use of this principle in the pirouette At the beginning, they rotate

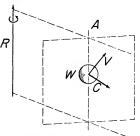

Figure 4. How the Coriolis force operates. The weight W moves in direction V. If whole system revolves around the sxis R in direction shown, W will appear to be under influence of a force in direction of C. Direction of C is perpendicular to plane containing A and V

slowly and spread out as much as possible. When they wish to speed up for the spectacular finish, they pull themselves inward. The force which causes this speeding up is known as the Coriolis Force. In general, it behaves in a very complicated manner, and cannot be adequately described without mathematics. However, the effect of it on the eddies inside the earth is to cause them to turn over slowly. Thus an eddy whose axis originally was radial gradually turns so that the axis points somewhat eastward. Actually, the description given here is a much simplified picture, and the real motion will be very complex and irregular. Nonetheless, in the random motion, there will always be the above-described tendencies. Meteorologists are very familiar with this force, since it causes the Trade Winds and the Gulf Stream. In this way, then, the Coriolis Force sets up an asymmetric effect (Figure 4) and a resulting thermoelectric current may flow.

Certain difficulties are present in the new theory. The greatest disadvantages lie in the imperfect knowledge now existing as to the nature of the earth's interior and the behavior of materials under the enormous pressures and temperatures known to exist there. All estimates of these things are extensions of knowledge obtained in a much lower range and are not likely to be particularly accurate when applied in this manner. But the new theory does provide a start on an old problem.

THE SALUKI EVERLASTING

ARCHING down through the ages comes man's love of hunting as a sport, and the pleasure he took in having about him some reminder of the companions of the chase. In a time when much attention is given to the preservation of trophies by taxidermy, the collection of hunting prints, and to bronze models of champions, ancient man is brought much closer to us when we find evidence of his similar devotion to his limiting dogs expressed in one of his earliest and most personal art forms Such were the engravings of his favorite Salukis hunting hounds on early stone stamp seals

These stone stamp seals were small, thick buttons or disks, sometimes with

knob handles, sometimes without, but almost always plerced so that they could be worn around the neck or attached to the belt by a cord through the piercing. On the flat side was cut some figure or figures which, when pressed into soft clay, left an unpression, just as our sealing-wax seals do today. These round, though sometimes square, impressions were men's signatures Later they appeared on clay tablets. Then the stamp seal developed into the cylinder seal which, when rolled across a soft surface, left in the clay an elaborate group of figures and still later carried even the crudely cut letters of the owner's name.

The seals of which impressions are allown at the right are from the joint excavations of the University Museum of Philadelphia and the American Schools of Oriental Research at the great city mound of Tepe Cawra in Northern Iraq near Mosul [Scientific American, Oct. and Dec., 1935 — Ed.]. They

come from Levels II and Mra and were found in house debra which is dated before 3500 s.c. The people who occupied the Vainted Pottery Peoples and they have left the stamp of their development in many parts of the Near East by their fine decorated pottery, and at Tepe Gawa by the advanced state of their architectural progress as well. Among the smaller things to play a part

Carvings Found in Ancient Ruins in the Near East Show That a Breed of Dogs Now Fashionable Among Fanciers was a Favorite there 5000 Years Ago

By W. H. NOBLE, Jr.

in their lives and which have come down to us, were stone gaming pieces, a pot tery holder of an obsidian razor blade (terminscent of our straight-edged razor), superb obsidian bowls showing a patience and technical attainment of high order in working in this stubborn material and, finally, a number of these

Modern drawings of some of the ancient seal impressions or personal "signatures" discussed in the text

small seals of which the impressions of only a few have been shown here.

Crude interpretations of the human figure, geometric designs, fish, and unidentifiable animals appear cut into the stone faces of the seels, but the one subject, and easily the favorite, in which they exhibit an impressive skill in portrature, is that of hunting dogs. These tall, slim, and uncommonly graceful animals do not present an easy task to the stone cutter, yet they are shown standing, seated, or in a playful attitude and you are definitely conscious that with early civilized man's technical ability went a great interest in and love of his subject. On the face of the seal on the opposite page —one of the best uncertied of the round swist—there are

as many as three of the dogs and with them are three animals, only one of which is easily identified, an ibex. Of another seal (right, center, in illustration on this page) only a portion of the face is preserved, and there we see the hunting Saluki with a smaller animal in front of him, poorly cut but with the small horus of the gazelle definitely protruding from its head The rectangular seal face in the same illustration presents a nice study in design, with the three dogs placed one above the other. Just what the objects are in front of them it is difficult to say; perhaps they are the heads of a two-horned animal, though these strange shapes may be merely "fillers," for we know that the purchaser wished to get his money's worth and insisted that the engraver fill up every open snace!

THERE is no denying the pride which these sportsmen of over 5000 years ago took in their sleek, graceful

hunting dogs, else they wouldn't have placed them so profusely on what must have been one of their fondest possessions—their stamp scals.

Strangely enough, today in the Near East, one of the Arab's greatest treasures is the same type of hunting dog—the Saluki. He does not, however, actually class his Saluki as a dog! If the modern Arab does not hate dogs, he ranks them very low in his estimation. Nor can he

be blamed, for the usual type of dog in Irak, Turkey, or in any part of the Near East is likely to be a ficrce, ungrateful and often cowardly beast-large, dirty, and untrustworthy. Partly, this is the Arab's own fault, due to his bad treatment and religious attitude toward dogs. The Saluki, on the other hand, is another matter He is more lithe and graceful than our greyhound, is larger and faster than our whippet and, above all, is very sensitive to human contacts. An American on one of the excavations in Irak wished to photograph a particularly beautiful example of the Saluki When asked to pose with his dog, the proud Arab master disdainfully refused, denying that it was a dog His insulted dignity could be soothed only when the American photographer obligingly agreed that this was in truth no dog, but an entirely different class of animal-a fleet and noble Saluki,

TODAY the Arab effendi saunters through the bazars with his heaut ful Saluki lieude him or smokes his water pipe in the coffee house with the lean animal stretched gracefully at his feet. At times he will even hestir himself to hunt the gazelle or the rabit. Then it is that the Saluki shows its greatest virtie, its marvelous speed With himsaster riding a horse at a gallop, the Saluki can be seen circling about him in great orbits with unbehevable swiftness, timing in mid-air with a leap when some prey is scented or else spotted with its keen eve.

The actual speed of these dogs is difficult to ascertain, though on Iraki roads one has been known to keep abreast of an American car when the speedometer read 42 miles an hour The driver of the car couldn't "step on it" any more Probably the Saluki could.

In the last few years American interest in these dogs has quite rightly increased by leaps and bounds. There is now an American Saluki Cluh, and at many of the leading dog shows on the Atlantic seaboard there are classes of Salukis. While their nedgrees are not

Ayesha, the modern Saluki mentioned in the text. She was brought to America by Mr. and Mrs. Charles Bache. Compare with the Salukis on the ancient seals

so old nor in such good order as some breeds, they have been accepted by the American Kennel Club.

The photograph reproduced above is of the famous Ayesha, brought to this country several years ago by Mr and Mrs. Charles Bache, of Philadelphia.

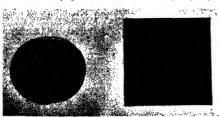

Stamp seals with pierced knobs for

who excavated many of the seals in Irak. Ayesha stands about 30 inches high and she thought nothing of leaping from the roof to the ground or, for that matter, of plunging through a plate glass door in a Beirut hotel, her knowledge of glass at that time being limited. She was entered with notable success in a number of shows in this country, though her par-

ticular kind was rare, being of a Koweit type. This principality is in Southern Irak on the Persian Gulf and breeds a somewhat more powerful animal.

As we follow the Saluki or his family history down from the Painted Pottery People, interest or cyidence of him is fairly slim. In Egypt, on the Old Kingdom reliefs in the Tomb of Tahotep, of the Fifth Dynasty, at Sakkara, we find an animal whose body is that of the Saluki, though the ears are slightly different Here a group is being held in leash by a servant who awaits their mater, while in another register they are shown attacking gazelles during a chase Persian miniatures show him delicately modeled and cream in color, accompanying his hejewelled and silken master. Morgan Stinemetz, in an excellent dog chart in Nature (February, 1939), reports that the Saluki first entered England in 1840 hut made little headway until imported from Arabia in 1895. After the Saluki's entrance into Russia in the middle of the 17th Century, "to slake a noble's thirst for fast dogs, was crossed with a collie-like native to provide the needed fur and so we have the Borzoi However, this example is a side shoot, not the main line of Saluki descent, and the latter is found in Arabia, not far from the earliest place of record 5000 years old

B UT it is back we must go to that mound of Tepe Gawra, which flow ished in the Land of the Two Rivers as long age as the 4th and 5th Millenna s. u. the standard of the Two Rivers as long age as the 4th and 5th Millenna s. u. they portraved them in their dags that they portraved them in their dags that they portraved them in their days them in their days the standard them is well that there is no dult about their descendants in the modern Saluk. These graceful animals bound and prance today. What of their masters?

The ancient seal at left does not look like anything in particular but its impression, shown at the right, reveals three Salukis and some other objects

NEW X-RAY UNITS FOR FIGHTING CANCER

HIGH-VOLTAGE X ray machines of revolutionary design feature the equipment of the Memorial Hospital for the Treatment of Caucer and Allied Diseases, in New York City. Recently dedicated, the hospital uses for radio-therapy a 1,000,000-volt X-ray

Operating one of the easily ma-neuverable 250,000-volt X-ray machines. These are similar to the 1,000,000 volt unit described in more detail on page 151 of this issue

machine as well as five 250,000-volt units. Notable for their exceeding compactness and maneuverability, all were developed by General Electric through collaboration among research laboratory scientists, Memorial Hospital representatives, and G-E X-Ray Corporation engineers.

OUARTZ-LIKE GLASS

AN entirely new method of glass manu-facture yielding products which can be heated to cherry red heat and then plunged into ice water without breaking has been developed in the research laboratories of Corning Glass Works, it was announced recently by Amory Houghton, President. The Corning management made clear, however, that while the Research Department had completed its exploration into the unknown and had established its findings beyond doubt, it will be two years or more before the products can be offered to the public

The weirdest point about the new and revolutionary process is that articles made by it shrink to less than two thirds their original volume yet retain their identity

Contributing Editor ALEXANDER KLEMIN

charge, Daniel Guggenheim School of Aeronautics, New York University

and suffer no distortion of form. This means a linear shrinkage of 13 percent. For in stance, if you want to make a nine-inch dish you first make one ten and a half inches in diameter.

The new Corning process consists of a series of contrasting operations and there are several alternative variations at the end which give an amazing variety of results In simplest terms, what happens in the main process of this A normal glass object such

Above: Molten iron, poured on new glass chilled by ice, has no effect on it. Right: A 12-inch disk shrinks 11/2 inches during proce ing. The glass is 96 percent silica

as a plate or beaker is made by usual melting and molding operations but with a spe-cial glass formula. Then, through a series of treatments involving final leaching with of treatments involving man reasung was delute nitric acid, part of the atructure of the glass is removed—leaving a skeleton, so to speak. Then, under further heat treat-

ment, the glass shrinks down to a volume which is a reduction of 36 percent from its original size. As a matter of fact, during the acid treatment, 36 percent of the body of the glass has been removed, 64 percent remains The surface feels rough to the touch but does not feel porous Actually at this stage it is filled with sub-nucroscopic capillaries or air spaces. On final heat treatment the glass body reaches a transparent, homogeneous state in which it is practically 96 percent pure silica. In this completed state the glass can be heated to a bright cherry red color, and then dipped into a vat of ice water with no injury whatsoever.

The outstanding significance of the new Corning low-expansion glass is that it will offer in an economical price range a material similar to fused quartz. A miniature pilot plant has been operating for several months To put the process on a full-scale basis would require at least two years, even assuming rapid designing and building, according to the chemists in charge.

PERMANENT GLASS-MARKING INK

THEMISTS can make an effective and permanent glass-marking ink by mixing equal parts of chromic oxide with powdered lead borate, and stirring this into a mixture of equal parts of water, alcohol, and glycerin, according to Solvent News. The amount of liquid used depends on the consistency desired.

After applying the ink with a pen and allowing it to dry, the glass is warmed in the vellow flame of a Bunsen burner, then heated to red heat in a blue flame. The

glass is finally allowed to cool, using the yellow flame to lower the temperature gradually.

The ink is green, and because of the limitations of the process, cannot be used on heavy cast glass equipment such as desicrators, reagent bottles or the like.

TAXES

DURING 1938 gasoline taxes represented an average of 24.83 percent of all state tax burdens in the 48 states.

DESTROYER "HAMMANN" TYPIFIES NEW STEAM POWER ERA

Tille ghout of many a windyammer and the wraits of outmoded streamtips must have looked with envy upon the U.S. Hammonn, news member of the Navy'n Beet tell' and pranced efforties when teeth' and pranced efforties yet approximately 38 knots in her builder's trials receilly, manned by an expert crew supplied by her builder, the Federal Shipbuild ing and Drydeck Company, a subidiary of

the United States Steel Corporation Sleek and streamlined from her water-hine to her bridge, the Hammann demonstrated for a group of newspaper and magazine writers the efficiency, economy, and power of high temperature high-pressure steam that drives her livin sets of main propulsion turbiness Slie performed as re-which were authorized under the 1937-38 Naval Appropriations Act

The story of the Hammans is a story of power, for she is literally a \$5,500,000 power house aflost Compressed inside her needle-like hull is power enough to lift the 300,000-ton George Washington Meniorial Bridge more than 160 feet an hour-provided of course that the power of her two turbing units could be harmaged to such a lask.

units could be harnessed to such a task
It is the story of the transition of marine
power plant designing from empirical en-

U. S S. Hammann is an identical sister ship to the U. S. S. Anderson shown above

gineering with low-pressure, low-temperature steam engines to the scientific development of high-pressure, high-temperature turbines based on some 20 years of research. The result is production of destroyers that are the most economical and fastest fighting ships of their sire on the Seven Seas.

If yudged by appearances, the Hamman is a "little fellow" for a big job, she's only 341 feet long at the waterline, 36 feet in her actrume beam, and she weight as eant 1500 tones not much heaver than a gun turret on a modern builtedby. But encosed in her steel shell the ship earness a compact power plant that appeareds in performance the west of many of the largest high-pressure of many of built to opener in big city mover stations.

The six main turbines on the Hammann weigh altogether only 55 tons, but are capable of producing about 27,500,000 fost pounds of work per second

SMOOTHNESS INDICATOR

A DEVICE so sensitive that it will indicate the differences in thickness of a fingerprint on a piece of smooth glass, has been developed by J. A. Sams of the General Electric Works Laboratova.

Known as a surface indicator, the instrument is used to determine the smoothness of metal or painted surfaces and indicates minute variations far beyond the range of the human eye. Variations of as little as 171,000,000 of an inch are clearly indicated.

1/1,000,000 of an inch are clearly indicated.

By its application, the surfaces of hearings or other moving parts of motors and the like, that are subject to wear, may be tested and

their smoothness indicated

The apparatus appears somewhat like a
phonograph with its iturable on which is
placed the object to be tested, and its sapphire-pointed stylus or needle that passes
over the test material as it revolves.

Small mechanical impulses are created as the hard point rides over surface in regularities. These impulses are then transmitted to an electro-magnetic pickup which converts them into electrical impulses. They are then amplified and transmitted to a recording meter where the surface characteristics are graphically indicated.

The stylus or needle is so sensitive that when it is placed on the revolving metal turntable, the invisible obstations established by a person whistling are shown on the recording meter.

SOLVENT RESISTANT GLOVES

THE LAW OF CONVEN-IENCE AND NECESSITY

MEMBERS of the Covil Aeronautics Authority, fere in number, have fame and montrous my more than and montrous have their toubles. Their all their also have their troubles. Their accessive for proposed auroutes. There is no longer a question of inducing a government department to establish mail service and then to grant a contract for that service on a hasis of competitive

Objects to be tested for surface smoothness are placed on the turntable

Eight years old, the Lieutenant de Vaisseau Paris is still in service

hidding, solcly, without regard to other considerations. Now, as Chairman Robert H Hinckley points out, much sounder methods are in vogue. He defines the granting of certificates for air routes in the following words. "The law applies the familiar doctrine of convenience and necessity Under that doctrine, in general, an applicant must show that in the territory to be served there is sufficient potential traffic to justify the service, and that the applicant is fit, willing, and able to perform it. We believe that th law requires proof that a proposed operation can eventually develop mail, passenger, and express revenue to the extent of assuring that the new line will not become a burden either upon the government or the community or the corporation proposing to operate it

A mass of new applications is even now before the Authority, with a gridron of a proposed new arlines. A tabulation of 48 applications from 24 different are services undicates that should all applications be granted, a total of almost 14,000 route miles would be added to the existing system of approximately \$5,000 miles. Nothing gives a better picture of the enormous scope of our train-port system— A K.

EQUIPMENT FOR SAFETY IN AIR TRANSPORT

WHEN people speak of aeronautical research they generally mean research
in aerodynamics, in the light properties and
structural siterath of the airplane, in greater
again reliability Certainly such research
is of innolumental importance, advantum reverted. But, as Paul Johnston, Editor of
southern, pointed out in a recent paper
presented at the Aeronautical Session of the
National Safety Council, there is another
type of re-search which is conducted by the
airline operators, individually or in co-operaion, which is not recondition practiced
by mathematicians or physiciats, but is of
copial importance as far as airline astery is

concerned
Thus, in conquering ice formation on the airplane, we find Goodrich continually improving its "over-shoes" or wing de-icers. Non-icing carbureters of the Chandler-Groves type are in service and being continually improved by the airlines. Wind-

shield wipers, with alcohol and other non freezing mixtures mechanically distributed over the windows, is another subject of investigation Improved fluids and methods for protecting the propeller against ice are now available

Radio developments are innumerable, and so well advertised that we need hardly touch upon them here. But there is a long list of other safety devices, some of them of humble character, which may not be as well known to our readers. Thus, upholstery and farm ture fabrics in the airplane are being fire proofed Birds have struck and broken windshields time and again; accordingly, wind shields are being reinforced. One transport company is testing bullet-proof glass for use in its windshields. The NACA, or venture engine cowls are being built of stainless steel to withstand corrosion and the effects of high temperatures Cockpits are being improved so that controls can never jam Hydraulic-pressure bench tests on engine cylinder heads are carried out to warn of possible failure. Metal particle detectors are inserted in engine lubrication lines, where such particles may cause serious damage. Bolts, nuts, and studs on plane or engine may be tightened up too much or too little; instead of relying on the skill of the nut into service.

The list could be continued. Any new safety idea is welcomed and investigated if it seems reasonable. Designers and inventors still have a fertile field ahead of them in airplane safety equipment -- A K.

FLYING BOATS HAVE LONGER LIVES

WE have read so much of the achievements of Pan American Arways, with the new Boeing Clipper, in establishing the first north Alantic are service, that it is hardly necessary to comment further on this historic subject. Less spectacular but also interesting is the recent flight of the French flying boat, Leutemant & Fusicous Paris, from Port Weshington, Long Island, to Biscaroses, France, in 34 hours and 14 minutes. There are two reasons why this hight is of interest. First, it is part of a series of survey flights being made by Air France. Eridently European companies will not leave the field solely to Americana. Second, the Vasseue Paris is eight years old, and is one of the largest flying boats in the world We used to think of aircraft as fragile vehicles, short lived due to depreciation or absolescence. The French boat has seen continuous service in various parts of the world, yet in cell, going among the control of the world, yet in cell going among the parts of the par

SODIUM LIGHTS FOR SAFER LANDINGS

W HEN fog and haze blanket an airport, flight operations may be emploid. In this new lighting system, three green manulecent lights, placed flesh with the ground, indicate to the plot the beginning of the rainway Then, at 100-foot intervals, sodium contact lights of amber color, spaced on each side of the rainway, indicate that the plane is over the first 1000 feet or more of the rainway. The haal 3000 feet of the rainway as distinguished by white reasoning the boundary there are there more green

Inserting one of the sodium light-

lights Such oppositely placed lights mark

out the runway in aplendid fashion. Besudes the actual arrangement of the Bights in relation to the runway, two sid-vantages are claimed. The use of sodium lights increases visibility under foggy conditions. Field cess at Akron indicate that the sodium lights were visible at 410 feet, when incanedoesnel lights were only visible at 35 feet. Again, all the light emitted from the condition of the property of the condition of the property of the condition of the pilot's eye. A. K.

EXHAUST HEAT TO PREVENT ICING

TCE formation in flight still remains a serious problem, in spite of the strides that have been made in preventing it. A technical note of the National Advisory Committee for Aeronautics states that the Goodrich de-icer (which removes ice forcibly and mechanically from the leading edge of the wing) does not function satisfactorily under some conditions. It has been frequently suggested that exhaust heat from the engine might constitute a fine "anti-icer," and now experiments by the Committee indicate that the idea has possibilities
A model all-metal wing of six foot chord

was placed in a refrigerated wind tunnel, in which the temperature was kept at 20 degrees, Fahrenheit, and where a wind velocity of 80 miles per hour was available. Natural precipitation was simulated by admitting water to the air stream through a spray nozzle Electrically heated air was led through an air duct inside the wing. and a fan was used to circulate the air inside the wing

The results of the experiment, though preliminary in character, were satisfactory Ice formation was effectively prevented by maintaining a skin temperature of 200 degrees, Fahrenheit, over the leading 10 percent portion of the wing. The temperature in the duet varied from 360 to 834 degrees, Fahrenheit Heated air velocities in the duct varied between 45 and 152 feet per second

Similar conditions could be realized by leading exhaust gases from the engine through the actual wing of an airplane Let as liope that either the Committee or some venturesome engine constructor will carry out a similar experiment in actual flight

NO ORDER OF LESS THAN A MILLION DOLLARS

THE airplane industry flourished during the World War, almost perished of inanttion after the armistice, had a boom period in 1929 or thereabouts, and then again fell on very bad times Now all airplane manufacturers, particularly those building military and naval aircraft are flourishing and receiving large orders. It is being said jokingly in the industry that no order under a million dollars will be accepted. For example, Curtiss-Wright in its Buffalo airplane division received recently an order of \$12,-872,398 for a large number of P-40 pursuit

planes, an example of which is shown in one of our illustrations. Some noteworthy items appear in the photograph. The liquid cooled engine is evidently coming into its own; the familiar radial has disappeared in this ship. Oxygen equipment permits long flights in the sub-stratosphere. Fillets between wings and fuselage are very large. The vertical tail surfaces are disposed below and shove the stabilizer, as a precaution sgainst spinning. The Pitot tube for the airspeed indicator is placed toward the tip of the wing and well shead so as to be free of interference. The cockpit has perfect visibility All performance figures are withheld, but it is quite clear that our designers are producing excellent military aircraft.

- A. K.

PETROLEUM

THE fields of Texas, California, and Oklahoma alone have pro-duced more oil to date than have all the fields in Russia.

LIOUID COAL

DRIVES A CAR

EXHIBITING the startling possibilities of their newest development, liquid coal, scientists of the Research Foundation of Armour Institute of Technology recently showed how it was possible to operate and drive a 1939 stock model automobile, a Pontiac, on coal This newest development in research is credited to Dr Francis W Godwin, Director of the Coul Research Division of the Foundation.

The most amazing part of the entire demoustration is found in the fact that the test with coal was made on a standard car engine without any changes of any kind in carburetion or in the ignition system of the motor, with the exception of the removal of

one fine-screen filter According to Dr Godwin, three different types of colloidal fuel have been used suc cessfully in the tests on the stock model automobile to date. The first of these fuels was a suspension of a specially prepared coal, ground to 300 mesh, in a mixture of gasoline, fuel oll, and lubricating oil. The

second test with the "liquid coal" was made with a suspension of the coal in a Diesel oil. The third test was made with a suspension of the coal in a very light oil. The more recent test and demonstration was carried out with a more elaborate preparation of the fuel A very light oil, or a form of range oil with a light fraction of hydrocarhous, was used as the vehicle, followed by special treatment with the coal, resulting in the suspension of coal of about 500 mesh

Stoking liquid coal in a motor car

In each case, before the liquid coal was introduced into the auxiliary fuel tank on the automobile, it was chemically stabilized in order to hold the coal in suspension

After the liquid coal had been prepared according to the process developed by the scientists, it was introduced outo the anxilsary fuel tank. The automobile was then started on gasoline and, after spooth running conditions had been attained and the motor had "come up to driving heat," the fuel system was changed so that the gaso hae supply was cut off and the liquid coal introduced in the carbureter. Thereafter the engine ran on bound coal, and the ear

ran without undue strain or sluggisliness. Although liquid coal is not a product that is ready for the market or, more specifically, ready for consumer use in automobiles, the possibilities as shown by the demonstration are important Especially is this fuel deairable for the home owner who has been concerned with the problem of heating. It was pointed out that this fuel has been used in many types of domestic and commercial oil burners during its development, and that the heat value per cubic foot, as proved by these tests, is considerably more than either coal or oil alone. It was pointed out that the new fuel will make use of the tremendous amount of "fines" which are at present a waste product at the mones a waste product which the coal producers often cannot even give away

BRILLIANT BLUE

OPPER phthalocyanine, one of a new a group of synthetic dyes and pigments which was recently described by M Dahlen, of E 1 du Pont de Nemours and Company, is a blue dye of remarkable brilhance, tinctorial strength, and fastness lt is replacing iron blues and various basic color lakes in printing tilks, and ultramarines in paints, lacquers, and enamels. It is also being used in producing costed and printed textiles, coated paper, colored hnoleum, and in rubber to produce any shade from deep reddish blue to greenish pastel.

One difficult problem solved by the pigment was the provision of a suitable blue

\$12,872,398 worth of these P-40 pursuit planes have been ordered

is easy to nibble and has a pleasant oily flavor, and includes the following seeds: coconuts, Brazil nuts, almonds, cashews, pis-

tachio nuts, pili nuts, paradise nuts, pine nuts, pumpkin seeds, water-lily seeds, sunflower seeds, and the versatile peanut The pecan nut, produced as a \$6,000,000 per year orchard crop in Georgia and from native trees in the Southwest, is being grown in such quantities that new uses are being sought, particularly for imperfect kernels. Recently, Professor T. H. head, of the University of Georgia reported to the American Chemical Society what is known of this nut, and suggested industrial uses for its component parts Pecan oil has a bland odor and taste, and, having marked stability against oxidation and even aunlight, has been suggested for use as a salad oil and in cosmetics. Delicious cookies and cakes were made from a base of flour and

pecan meal, from which the oil has been

Above and below. Two views of the rotary fish screens in the Yakima River, described below, in which paddle wheels turn the cylindrical barrier screens

for three-color printing. Another application is in the production of an exterior paint. The new paint does not have the tendency of previous blue-tinted paints to fade quickly when exposed to suplight

ROTARY FISH SCREENS GUARD YOUNG SALMON

W ORK was completed recently on what thorities to be the largest batter of rotary fish screens in the world, installed across Wapsto dich at Parker, near Yakima. WPA's participation in the project involved supplying the labor, for which \$35,400 in Federal work relief allocations were invested.

These screens were designed to prevent young salmon, en route from headwaters of the Yakima River to the Pacific Ocean, which find their way into the huge ditch, from going into the irrigation laterals to destruction.

A battery of ten cylindrical screens spans the entire width as a barrier in the dutch. Each screen is 12 feet long and 13 feet in diameter. The flow of water in the dutch turns separate paddle wheels directly connected to each cylinder. Continuous turning prevents the screen from being clogged with mud and debths. By-pass channels lead from a bank of the canal, just above the screens, back to the river, to allow the altimon finger-

lings to continue their journey to the ocean. United States Bureau of Fisheries experts and other fish authorities state that the general instinct of the salmon is to return to spawn as an adult to the stream of its origin. The Indians foresee even a more happy fishing ground than in generations past, as a result of the fish screens.

RUB-LESS METAL

CLEANER

A NEW metal cleaner that instantly removes, by chemical action, stains and
oxides from chromium, copper, braas, silver,
and other metals, has been announced by
Rapid Electro-plating Process, Inc., to be
sold under the name of "1-Second" Metal
Cleaner. It is applied with a brush and immediately waped off, no rubbong is required

The new liquid cleans hard-to-reach places, does not soil hands, and has no

offensive odor It is said to contain no caustic; is non-inflammable, will not etch or harm metals; has three to five times the covering power of ordinary polishes, and, since it can be applied with a brush, will clean surfaces inaccessible to hand-rubbing methods.

The cleaner can be supplied either with or without abrasive and is designed not only for use in public buildings, households, and automobiles, but also for industrial operations where it is possible to wipe off excess cleaner after application.

BREATH

THE average human being exhales three pounds of carbon dioxide gas per day. To break down this exhaled gas and return oxygen to the atmosphere three large trees are required.

Nurs

A NUT is an "indehiacent, polycarpellary one-aceded fruit with a woody pericarp, developing from a syncarpous ovary." The acorn, hazelaut, and chestnut are true nuts, as are walnuts, pecans, hickory nuts, butternuts, and becchauts. But by more popular definition, a nut is any hard-shelled seed that contains a kernel that pecan breakfast cereal appears to be under

Industrial use of the pecan is predicated on the success of a new floatson method of separating the kernels from the shells of the cracked nuts, by agitating the mass vagorously in a salt brine, after which the kernels float and the shells ank. This may reconstitute the shell of the cracked nuts the shell sank. This may inchanize an industry hintero peculiarly dependent upon chesp hand labor. Unformately, the method recently developed in California for automatically cracking analust by miniature explosions cannot be applied to pecans. It will be recalled that in this method of a mixture of accession cannot be applied to pecans. It will be recalled that in this method of a mixture of accession cannot be applied to pecans. It will be recalled that the method that the subject of the state o

The per capita consumption of peanut is about sight pounds pract in the state of the control of

butternut, are not commercially significant, but are the property of the small boys of the land.

New nuts are added from time to time Out of exotic Hawaii now come limited quantities of the macadamia nut, a delicacy to tempt the palate of the epicure. Cashew nuts were introduced into America not many years ago by an enterprising and imaginative food chemist, who found them in wide use in India. The cashew is a relative of the poison ivy and Japanese lacquer plants, and parts of the cashew plant, if touched, would poison most people, yet the nut kernel, after being Frenchfried in hot fat, is a delicious tidbit, notable for its tenderness and sweetness. While at present the cashew nut is being exploited almost entirely as an edible nut (30,000.-000 pounds per year of the kernels are consumed), the shell contains a substance which may eventually become more important industrially than the kernel itself. This substance is a resinous liquid which, when chemically treated, forms products which are of marked utility in the plastics industry

The almond is practically a soft-shriled procedu-sion that has a pleasing high-proton kernel. Few other must have more than 10 or 15 percent of proteins, but contain from 40 to 75 percent of fast and small amounts of starch and sugar. Pecan means are the richest in fat of all nut meats, with Parill nuts, filters, and waluts not far hard and the are a highly concentrated food, and was a highly concentrated food, and contains the contains a support of the contains the contains a support of the contains the co

The coconut tree is credited with being by far the most valuable of all the food trees of the world, and is of vital importance in the tropics. The prosperity of the South Sea Islands rises and falls with the demand for copra, or dried ecconut meat, which is the source of coconut oil This oil is used in immense quantities for soapmaking and in oleomargarine, and the residue is valuable concentrated cattle food Because of excise taxes placed on such oilbearing nuts as the coconut and palm kernel, other nuts with strange names are finding a large North American market. In this group are the babassu nut, the colume nut, tucum nut, ourscury nut, and the murumuru nut, all South American.-The Industrial Bulletin of Arthur D. Little, Inc.

WOOL

TWENTY-five million pounds of wool, the product of 3,000,000 sheep, are consumed by the automobile industry in an average year.

DIGESTIBILITY OF

STRAW

STRAW contains large quantities of carbohydrates which can be only partially digested by farm animals. Various attempts have been made to increase the digestibility of straw by some pre-treatment.

In the course of an investigation of the problem, oat- and wheat-straw were treated with caustic-soda solutions of varying strengths and for varying largets of

Heat results were obtained with a 1.25 percent solution and an immersion period of 20 to 24 hours without heating. With

BURIED TREASURE FOR THE 70TH CENTURY

by Westinghouse

Many people have asked us how the Westinghouse World's Fair Time Capsule came into existence. Why should an electrical company be so interested in what the people of 5,000 years hence think of us?

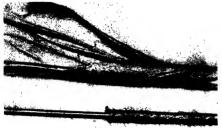

It all started with the slogan of the New York World's Fair. Most people, we knew, were thinking of "The World of Tomorrow" in terms of ten or more years. Why not, somebody suggested, take a real leap into the future?

Groups of scientists, to whom we appealed for advice, applauded the idea of preserving something for the future; said it was too bad the Egyptians, and the Sumerians, and the Mayas hadn't been as thoughtful. Librarians, printers, historians and others helped with suggestions for the Book of Record of the Time Capsule, which is expected to preserve the story of the Time Capsule, which is expected to preserve the story of the Time Capsule for future generations. A committee of engineers decided that one of the newest allows, Cupaloy, could be counted on to resist corrosion, pressure and other hazards for many thousands of years. By using the latest techniques, such as microfilm, we were able to cram an astonishing lot of information, and several hundred articles and materials of common use, into the Time Capsule.

Through it all, we had the help and enthusiasm of many of the country's foremost scholars and scientific men. In fact, it was an illuminating experience to learn how pleasantly men and women in all walks of life can cooperate in the working out of a simple, uncommercial, imagination-provoking idea. It was an emotional experience, too. On the day when the Time Capsule began its long rest, at the site of what is now the Westinghouse Building at the New York World's Fair, more than one person in the audience wiped tears from his eyes when the glistening Cupaloy Capsule began its solemn descent.

But what's the nub of it? Well, we think the Time Capsule attracted such wide and kindly interest because it is a sort of symbol of our age; an age of which most of us are intensely proud in spite of many difficulties and shortcomings. An age that not only believes it has something of great value to preserve and pass on to the future, but equally significant, one that knows how to preserve it—at least the material part of it.

We hope the "futurians" do find the capsule, of course. If they are so far advanced that the objects we have left seem only toys to them, we think they will nevertheless be interested to know that an age otherwise pretty intent on its own problems, still found time to think of the future.

Old and New: Spiral paper (top) and new molded pulp wire insulation

the volume of solution used, this represent ed 10 pounds of caustic soda per 100 poundof straw The starch equivalent per 100 pounds of straw was more than doubled by the treatment

Treated oat-straw fed to fattening bullocks resulted in a daily livestock gain of just under two pounds over a period of 62 days .- Nature

MOLDED PAPER INSULATION

T ISING a new process of producing paper insulation on a telephone wire instead of wrapping it around afterward, engineers of the Western Electric Company have just created a cable containing 4242 separately insulated copper wires

The previous top in wire packing was 3636 wires to a cable 2% inches in diameter The new cable is no larger but contains 606

The heart of the new development is a process for forming paper pulp directly on groups of 60 wires passing through a bath of pulp These strands are twisted two wires to a pair and assembled into the cable which finally is dried out in vacuum ovens

The saving in insulation thickness per wire is only three one thousandths of an inch but when repeated 3636 times in a single cable it results in 100m for 606 more-Science Service

ASPHALT ALUMINUM

PAINT

ASPIIALT, tung oil, and aluminum paste have been combined in a recently announced paint which is said to be suitable for either inside or outside application. The paint comes ready mixed and may be ap plied direct from the container

INDUSTRIAL PUMP MADE OF GLASS

HANDLING of commercial quantities of corrosive acids and chemical fluids has long been one of the most difficult problems of the chemical engineer. Many of these fluids quickly destroy metal pipes and pumps, and thus make some processes costly Also, minute traces of corrosion impurities may completely change chemical reactions and hence the resulting product Pipes of glass have for many years solved the problem of conveying corrosive liquids, and now a pump of glass, perfected by Corning Glass Works, marks a further step in the safe and economical handling of such liquids

This new pump is of the centrifugal type Not only the casing, but also the rotating impeller, and all parts in contact with the corrosive liquid are of clear, clicmical-resistant glass. The rotor is accurately bul unced, and, running at high speed without appreciable vibration, the pump readily handles 6000 gallons of acid or other liquid per hour and will deliver it 70 feet above the suction level

Neither boiling temperature nor strong

Above: Glass casing, impeller, and back plate of the new industrial pump. Below: The pump assembled with direct-coupled driving motor

acids affect the glass of which this pump is made. The problem of pumping hot hydro-chloric scid can thus be solved economically for the first time

So clear is the glass used that the interior of the punip may be watched while it is in operation. Should cleaning be required. the whole interior of the pump can be laid open in a few minutes. All acid solutions (except hydrofluoric or glacial phosphoric acids) may be used without fear of pitting or injuring the hard chemical Pyrex brand glass surface Reassembly after cleaning is quickly accomplished and the proper adinstruction of parts is practically automatic

STOP, LOOK, LISTEN

APPROXIMATELY 35 percent of accidents at highway-railroad grade crossings during 1938 resulted from operators of motor vehicles crashing into the sides of trains.

CLAY FILM

SUBSTITUTES FOR MICA

DEVELOPMENT from common clay of a film which looks like celluloid or Cellophane and which can be stored in water for an indefinite time without de retiorating, was announced recently at the Sixteenth Calloid Symposium of the American Chemical Society, at Stanford University, by Professor Ernst A llauser of Massachusetts Institute of Technology and Miss D S le Beau of the Dewey and Almy Company.

In sheet form, the new material, Profes sor llauser declared, promises to supplant sheet mica, a strategic military material, important in insulation, which the United States has to import from foreign countries in thousands of tons annually.

The water-resistant quality of the new film is the result of research just completed, Professor Hauser said The first self-supporting, coherent sheets made from pure clay about a year ago swelled and finally disintegrated in water Called "alsifilm." the material nevertheless had many "amazing" qualities, according to the chemists. Being entirely composed of inorganic matter, it was non-inflammable and would stand extremely high temperature without de-

organic solvents in general, as it basically contained aluminum or magnessum silicates. In dry condition, it exhibited very satisfactory electric unsulation properties, which, however, dropped rapidly as soon as the film picked up traces of moisture.

The new water-resistant film overcomes this drawback and retains all of the good qualities of the first clay film. Both in regard to its general properties and its actual composition, the material, Professor Hauser pointed out, is comparable with miea.

The alsifilm can be produced in any desired size and thickness and can be made decidedly more flexible than natural mica

RAILROAD TRUCKS

AMERICAN railroads have 53,000 motor trucks in terminal transfer, inter-cut, and store-door delivery service. This number of trucks exceeds the number of locomotives operated by the railroads.

ELECTRIC OFFICE SECRETARY

A MECHANICAL secretary which takes dictation, write eletters that talk, answers the phune, records busness deals underscence, reads the lows to sleep, and acts as watchman, has been produced by a talchments covered by 32 patents, the native performs additional districts which the performances, also such as a property of the performances, and other performances are performed to the performances and other performances are performed to the performance of the pe

The machine, briefly, is a ware recording and reproducing unit a bala and compact and reproducing unit a bala and compact and reproducing unit a bala and compact and records a 780 on a collar of Cellophane-like material which costs five certs and as on line that three of them (containing about 25,000 words) can be folded into an exvelope and mailed for a three-cent stamp. A supplementary device makes are also a containing about 25,000 words) can be folded in a containing about 25,000 words) can be folded to a containing about 25,000 words) can be folded to the containing about 25,000 words) and the containing a containing

These records last indefinitely and may be folded flat and filed, to be played when needed. Or they may be transcribed onto typewritten pages by a stenographer using either loudspeaker or headphones.

Adapted to 110 volt direct current, the

Records made by the electric secretary are thin, flexible, mailable

Waldorf Rates Have Not Increased!

THE WORLD'S MOST EXTENSIVELY
AIR-CONDITIONED HOTEL

It really doesn't cost any more to stay at the Waldorf . . . in fact, luxury and service considered, the Waldorf costs less. One of the added satisfactions of your visit to the New York World's Fair is that in choosing the Waldorf, you pay only our standard rates!

And stopping at the Waldorf is, in itself, one of the never-to-beforgotten experiences of your visit to New York.

GERMICIDE PROTECTS SPORTING EQUIPMENT

THE problem of sterilizing and deodorising sporting equipment long has troubled proprietors of skating rinks, gymnasia, and swimming pools. Taking a tip from the WPA., many now are using Wyandotte

Steri-Chlor, an effective germicidal agent

that may be applied in powder or liquid form.

Experience of the federal government has proved that this product is excellent for dismiceting boots that are worn by many workers. A half-teaspoonful, sprinkled inside each shoe, retards the spread of athlete's foot and amiler diseases

The product is stable and will maintain uniform strength. When used in solution, its low temperatures, providing the highest degree of sanitation.

Because it harms only germs, it is widely used in sterilizing fountain and dairy equipprotecting all types of sporting goods.

PLASTIC COMPOUND FROM

SUGARCANE BAGASSE

A PLASTIC compound made from the asso, one of the country's important agricultural waste products, has been manufactured by chemists of the United States Department of Agriculture at the Agricultural By Products Laboratory, Ames, Iowa. The chemists estimate that this new compound

Sugarcane bagasse plastic may be molded in a wide variety of forms

can be manufactured for less than half the cost of the cheapest synthetic plastic compound now on the market.

Molding compounds may be made from the bagasse by three methods The first, and cheapest, is hydrolysis with acid. Counting the cost of bagasse at eight dollars a ton, baled and delivered at the factory, the chemists estimate that a plastic compound can be made by this method, in which the cost of material will be slightly more than two cents a pound. Plastics made from the compound, while not so strong as some synthetic products now in use, are quite moisture resistant and would be suitable for molding bathroom tile for both floors and walls. They apparently have the wearing ability of wood and may be sanded and re-polished through the entire body.

The second method is hydrolysis in the presence of aniline, a coal tar derivative. The material cost of plastics from this process will be more—about 41/2 cents a pound but they are as strong as plastics now in use. In tests it has resisted bending pressures up to 9000 pounds per square inch. They are slightly less water-resistant than plastics made by the first method, but do not warp

and may be sawed, drilled, and, with care, nailed. These properties suggest uses as card table tops, desk tops, and building panels

Treating the bagasse with sodium hydroxide and furfural is the third process. In quality, plastics from this method are about midway between the other two. They flow better and mold at 2500 pounds per square inch compared with 3500 for the second treatment. They may be put to the asame uses as the plastic from the second treatment.

Either of the plastics made from the last two processes do not shatter easily. In fact, neither breaks when struck hard enough with a hammer to cause a dent.

It is possible that other farm waste materials, such as cornitalis and straw from small grains, may be used in making plastics by the same processes, the chemists report.

TOLL

DURING 1938 in the United States there was one accidental death every 5½ minutes. Non-fatal injuries suffered in accidents occurred one every 3 seconds.

JUDICIOUS JIGGLES

VIBRATION to like a surious areak in that it can be one man's near tor another man's posson. Many engineers are troubled with machines that shake too much, others are spending their best effects. in building mechanisms for the sole purpose of creating whration, but vibration whose intensity and frequency are under continuous countrol. There are numerous points in industry, notably in the fields of construction, mining, chemical processing, jugging or even wever shaking as a necessity, declares the Industrial Buildean of Arthur D. Lattle, lace

When the thing goods are electrically operated, the source of power is generally a magnet, for it lends useff to mechanism which are simple in construction, with few oling points, and with correspondingly few points to wear or cause trouble. The rug-gedness of such tools is indicated by the fact that a large outlet for them as in ham-less than the control of the control of the district in th

The conveyor line is a frequent user of magnetically induced vibrations. Not only will relatively tractable materials like said move amouthly down a properly oscillated trough, but also obdurate objects such as dig biscusts or metallic fasteners which, under ordinary conditions, may not "flow" at all. Although the eye seen only a uniform progression, the goods are actually jumps. (The dog biscustor—and articles less than the progression of the pr

By means of a rhoostat, the rate of feeding can be varied from, say, 10 tons per hour, as in one application in a smelling plant, to a slow dribble. Vibrating conveyor feeders are particularly useful in conjunction with automatic weighing devices, because the close control possible allows an operator to feed rapidly until the scale beam trips, then to stop the flow of material instantly In spite of the wide use of magnets in other fields and the accumulation of much empirical data, there are no comprehenave formulas which permit the ready calculation of optimum dimensions for a given condition. Experience during the past decade, therefore, has led to steady improvement in details and to the exertion of progressively greater forces for the same movement of the magnet armstore. A more basic improvement has been the application of "power pulses" to energize the magnets Engineers attempting to avoid of power through their apparatus, builderof electromagnetic vibrators want, and have obtained, power that comes in spurt-The simplest way to supply the magnets with oversized "quantums" of energy sep arated by periods of no current flow is to ase so-called half wave received alternating current (produced by passing alternating current through some electrical valve that sllows current moving only in one direction to pass through it)

A recent and important advance is the use of pidese created by condense discharges, a method that allows great flexibility in the frequency at which the pidesare supplied. Dividopments in large capacity let frome tides permit the original source of power to be either alternating or direct current, and in this manner make control of the condenser discharges commer cully feasible.

The resperimenent of print makes the prediction of applications for this increased versatility a dange core-pastine, but magnetic and mining industries. Electrically wheat of series have been found particularly resistant to "blinding" or wedging of the material between the wires

Vibration is necessary in making pulp fibers mat into a sheet of paper, it is also being used in the placing of concrete. Satisfactory consolidation can be obtained with lower water-cement ratios than is practicable with hand-placed mixes, and physical properties are correspondingly better Artificially induced vibration has even proved to be a valuable means of testing laboratory specimens and completed structures such as bridges, buildings, and water tank towers. Oscillators are attached to the structure, and measurements are made of energy input and the degree of dampening. From the readings can be deduced such dynamic properties as endurance limits, periods of resonance, and the existence of structural defects.

In these cases, as in most others wherevibrations are deliberately created, no random shakes will do, but it is necessary to provide oscillations which can be adjusted to meet variations in the conditions or to give optimum results.

COPPER-BEARING CEMENT

A COPPER-BEARING cement, recently announced, appears to have possibilities of great usefulness in making "composition" floors, stucoe, and mortar for tiles and glass brick, reports Highway Research Abstracts.

Finely divided copper incorporated with "caustic" magnesia (not the dead-burned MgO) and mixed with a solution of magnesium chloride, produces in the mixture a

synthetic mineral that has good resistance to weathering. Thus compounded, the prod-uct possesses the advantages of flexibility. nct possesses the advantages of hexamity, resilience, and adhesiveness without the dis-advantages of poor weathering, efflorescence, and incompatability with lime.

Strength of the cement is high-several times that of Portland. The two materials do not compete, however; the copper-bearing cement, because of its higher cost and high heat of setting, is not intended for massive work, it supplements Portland cement.

How admirably the cement supplements and complements other building materials is indicated by a statement of some of its properties and uses It is not damaged by water It bonds perfectly with a great many substances; for example, its adhesion to sandblasted glass is more than 100 pounds per square inch It can be troweled, brushed, or sprayed into position, Setting is very rapid As a masonry paint it allows the material underneath to "breathe." And it will take almost any kind of filler or aggregate saw-dust, marble, asbestos, or what not.

THE giant turbines of a luxury liner use almost 32,500 barrels of fuel oil on a transatlantic erossing.

MIDGET MARINE RADIO TELEPHONE

F OR the safety and convenience of those thousands of yachtsmen who put out to sea in small boats, the Western Electric Company is introducing a low priced, midget marine radio telephone so simple to operate, so reliable and small, that it may be com-

pared with the familier telephone ashore The little instrument is designed to link those aboard the craft with the telephone system on land, with the Coast Guard, and with other radio-equipped boats.

To make a call with the new instrument. the user merely turns an "on" switch which places the equipment in operation, presses a "talk" button contained in the handle of the handset, and gives the telephone operator the number desired. Calls coming from shore, or from other boats, are signalled by a loudspeaker contained within the instru-

ment. The loudspeaker may be switched off during the subsequent conversation. Provision may he made also for "selective

Provision may he made also for "selective calling." A host so equipped is assigned a number, and its equipment maintains a contunuous, silent watch, to receive only calls that may be directed to it. When the shore station operator dials its number, a telephone bell rings exactly as on land.

Built in a single, self-contained unit, and designed to occupy less space than a small designed to occupy less space than a small overnight bag, the instrument is easy to fine a small, Radio transmiter, receiver, power conversion pack, and built-in loudspeaker are all assembled in a special metal cahnet that all assembled in a special metal cahnet that is finished to resist corroson, and only three electrical connections are required for installation: the antenna wire, ground, and power supply.

The device may be operated from a six of twelve will hattery or it may be simply adjusted for use with other voltages. The insamitter operates on any one of four crystal-controlled frequencies. By merely changing the quartir plates, frequencies other than those originally selected for the transmitter may be substituted, within the range matter may be substituted, within the range matter may be substituted, within the range unent is required when making the change. The receiver, too, may be crystal-controlled if desared, which eliminates the inconvenence of "shaling" for inconing calls.

Specially trained personnel is not required to operate the equipment. The regulations of the Federal Communications Commussion of the Federal Communications Commussion permit the operation of radio telephone equipment in manne service by persons holding a third class radio telephone operator's itemse which calls only for an elementary knowledge of the radio laws and regulations, and familiarity with the method of operating the equipment.

PAINT ON A WATER-BEADED SURFACE

O RDINARILY, paint must be applied to a dry surface to furnish a satisfactory and permanent finals. This rule need not always be followed, say the manufacturers of Werk-Kladle paint. They claim that their product will adhere perfectly to wet surfacer, as well as dry, and will chain-induce the need for temporary shatdowns or many the contraction of the working hours due to wet

The manufacturers state that the mate-

NEW STEAM

POWERFUL steam generator no larger A than an incandescent lamp, and similar in appearance, has just been announced by the Westinghouse Lamp Division, Westing With a thermal efficiency of 90 percent la cause the heating coils are directly immersed in water, this flash-type of heater can generate superheated steam from cold water in less than 15 seconds It is made in 1000. 1500 , and 2000 watt sizes, with evaporating capacities up to 57 pounds of water per hour, and can superheat steam to 350 de gress, Fahrenheit

The cylindrical case of the diminutive steam boiler, 9¼ inches long over all, is made

Midget electric boilers generate steam after 15 seconds of operation

of transparent glass, capable of withstanding an internal pressure of 25 pounds per square meh It is provided at one end with two heavy electrical terminals, sealed directly into the glass. The chemical-resistant glass 19 capable of withstanding mechanical stree and will also withstand being transferred mstantaneously from cold to boiling water, or vice versa, without cracking. A threaded pipe is sealed into the opposite end of the envelope as a steam outlet. Resistance wire coiled on an insulating core occupies most of the interior of the heater, leaving, in fact, space for but five ounces of water at a time

The generator may be used for many purposes for which either no steam supply has been available or where the economy or convenience of the new method of steam generation is outstanding. The steam generated by the new device may be used for the sterilization of dishes, glassware, instruments, utensils, clothing, cloths, toilets, and furniture. It may be used in the process of steam distillation often necessary in chem ical laboratories and in small chemical plants. It will furnish a convenient steam supply for pressure cookers and small steam ens, and can be used to supply industrial

A PROBLEM FOR THE MATHEMATICAL READER

FARMER tethers his cow to a stake A driven at the edge of a circular pasture, 200 feet in diameter How long should the

rope be it the cow is to be allowed to graze one half the area of the field?

This problem is offered by Lieutenant Commander Leonard Kaplan, United States Navy, to readers who enjoy wrestling with things mathematical No prize is offered for its solution. The correct answer is 115.87 feet but the solution-which is the part having chief interest to the mathemati cian-will be published in this department next mouth

Lieutenant Commander Kaplan was the author of five problems offered in our April. 1939, number, page 219 The answers were given in the same number, on page 251, but the solutions were not published hecause they were so long. The solution to the above problem is not so long and will be published In the meantime, please address all correspondence regarding this problem to Lieutenant-Commander Leonard Kaplan, in care of Scientific American, 24 West 40 51. New York, N Y, and it will be forwarded unopened.

steam for other small-scale processes. Used as a still, it could produce on short order lim-ited supplies of distilled water for drinking, for garages in isolated places, or for medicinal purposes The generator can be used to raise the temperature of water to boiling, for diskwashing or for general use as a domestic hot water supply in dwellings

TO REMOVE SILICA FROM WATER

MOST natural waters contain silica which, if the water is used for boiler feed purposes, may react with any calcium present to form a hard deposit of calcium silicate. If the silica content of the water can be kept below five parts per million, the possibility of its concentration and subsequent precipitation as silicate scale is greatly reduced.

Data recently published by the National Aluminate Corporation indicate that silica may be removed from water by treatment with hydrous aluminum oxide and that the oxide may be prepared from sodium aluminate. It was also found that pH control is necessary for optimum results.

KID PICTURES

DICTURES of children know no seasons. They furnish one of the most a solution in all photography in any mood, at almost any time, children are "available" for picture-making and need little urging, if any. The matter of dress, too, is hardly of any consequence, their mothers to the contrary notwithstanding. In fact, "dressing up" the children for picture-making is one of the chief problems the photographer has to combat Not only do the children often appear stiff when subjected to these embellishments, but they fail to behave naturally, with the result that the picture is, in some sense, a failure, no matter how good it may turn out to be technically

So take your kid pictures when, as, and of the opportunity occurs for unusual shots.

"Gee"

Move close for pictures of children in order to reveal their childish expressions. Avoid contrasty or low-key lighting as much as possible. Don't worry about freckles or lost teeth, but make the most of them. Get them candid wise or let them pose themselves naturally, in the latter case perhaps aided by a hint or two from you. Babies will give no trouble in this regard because they don't know what you're about anyway. Don't spare film when the kid shooting

16 good. Although occasionally you will get just the right expression and pose the very first try, the chances are that you will have to take several in order to afford a selection later on. Any camera will serve the purpose and the use of the enlarging

"Little Miss Homebody"

process will make up for any lack of ability to come closer with your particular lens equipment. Where it is found desirable. some diffusion under the enlarger will frequently help to improve the result by softening sharp outlines. Watch out for good backgrounds when you can, but since you cannot always choose, it may sometimes be necessary to shoot against a disturbing background or not to shoot at all. Such a picture as "Gee!", for example, either had to be made as it was or be lost altogether. Illustrating this piece are a few pictures of children made on different occasions.

"Hi, there!" was one of those impromptii things that make the photographer's life a happy one. While we were idling with the camera towards the end of a busy picme day, a mother and her baby, friends of our group, came along to join us. As they reclined on the grass conveniently only a few feet away from the camera, we shot head on from ground level just as the baby was exchanging smiles with someone standing back of us. The pose of the mother's with the animation expressed in both faces. seemed made to order.

A week-end visit with friends produced "Little Miss Homebody." One of the secret objectives of the trip was to make a picture of the little daughter of the couple we were visiting, but she was an extremely active child and we had almost despaired. Finally, just as we were about to leave on a few hours' auto jaunt into the country, she sat down in a big chair by a window There was not much light coming in, but opportunity was knocking and we had to make

"Pale"

the best of things Setting the eamers on the window sill to steady it and asking the subject to hold still "for a second" we hararded a shot at 1/5 of a second, //3.5 lens opening. The negative showed the hands sharp, but the bead had moved slightly. The expression and the pose were so charming it seemed a pity to lose the picture just because of a little movement of the head The solution came in the use of a diffusion lens during enlargement. This effected the desired compromise between the sharp hands and the "soft" face definition, besides affording a pleasant and desirable atmospheric effect.

"Suste" was also enlarged by diffusion. this time in order to minimize the harshness of the high-lighting as well as to assist in reproducing the mood of the subject at the time the picture was made.

"Gee!" was another picnic shot and was ne of a group we shot "from ambush." The boy knew the camera was present but appeared to ignore it. At the particular moment this picture was made, he was listening wide-eyed to the sound of an air-plane passing by. The person sitting by him moved back quickly so that while the background is somewhat cluttered up, the boy's face and figure predominate. If there were more lessure time than we have at the moment, the paper negative process could be profitably employed in removing most of the objectionable background

"Pals" was shot against the clouds from an extremely low position. More of the figures was included than shown in the picture, but cropping under the enlarger enhanced the effect by bringing the faces into greater prominence.

HAVE YOU TRIED CONTRAST FILTERS?

DARK sky standing out in stark con-A trast to white clouds is not true to nature, of course, but there is no doubt as to its pictorial effectiveness. The yellow

PRIZES

E VERYONE who owns a camera bas a chence of winning a valuable prize Plan now to entar your prints in this contest. You may entar any or all of the three divisions, but not more than two prints may be aniared by one contestant in any one of the divisions.

Specific rules for this contest are published below. Be sure to read them before you submit prints.

RULES of the Contest

- t The groups will be judged independently on the basis of pictorial appeal and technical excellence The decision of the judges will be final In case of a tis for any prize, duplicate prizes will be awarded to the tying contestants
- 2 Prints must not be smaller than 5 by 7 or larger than ii by 14 Prints need not be mounted, but may be st the contestant's option
- Photographs must be packed properly to protect them during transportation
- 4 Non-winning entries will be returned only if sufficient postage is included when the prints are submitted
- 5 Each entry must have the following data written on the back of the print or mount Name and address of contestant, type of camera, and film enlarger and namer used
- 5. Contestants may submit no more than two prints in each group, but may enter any or all groups
- enter any or all groups

 T. Prints must be in black and white
 Color photographs are not eligible
- 5. Prize-winning photographs will become the property of Scientific American, to be used in any manner at the discretion of the publisher
- 9 Scientific American reserves the right to purchase, at regular rates, any non-winning entry
- 18 No entries will be considered from professional photographers
- professional photographers

 e 11 All entries in this contest must be
- in the hands of the judges by December 1, 1939 Results will be announced in our issue dated February 1940 e 12 This content is open to all amateur
- It This context is open to all amateur protographers who are not in the employ of Scientific American

Remember that these prises are to be given in each division—or a total of six watches and six enlargers plus its subscriptions to Belentific American, totaling \$1,327.35 in value

 Watch winners may make their own selection of pocket style or gentleman's or lady's wrist watch.

Submit Pictures in ANY or ALL Three Divisions:

Division 1. Human—including portraits and other camera studies of people.

Division 2. Landscapes—including all scenic views, close-ups of parts of iandscapes, seasoapes, and so on

Division 3 Action—including all types of photography in which action is the predominating feature In each division there will be prizes of two Longines watches—"The World's Most Honored Watch"—and two Feders! Eulargers, as well as five Honorable Mention

Awards

This Contest Closes Dec. 1, 1939—All Entries Must Then Be in Hands of Judges

THE JUDGES:

McClelland Barclay, artist ivan Dmitri, artist end photographer Robert Yarnali Richie, commercial photographer

medium filter is still the most useful and the most convenient for the purpose. All we have to do is double the exposure or open the lens diaphragm one stop larger than would normally be required without the filter. But a deep yellow filter, requiring only three times the exposure, when using panchromatic film, or an orange, requiring about four times, or a red, calling for six to eight times normal exposure, will provide more dramatic sky backgrounds, though at the cost of over-correction. The disadvantage of using these contrast filters is the relatively long exposure required, but in these days of very fast film emulsions, anapshot exposures may be had even when using red filters.

FOR THE NATURALIST

Wilatr's wrong with this picture of snake's eggs? One person tells us the eggs look very large when as a matter of fact they were quite small, roughly a little inder 2 inches in length. Some fa-

"Snake's Eggs"

milar object, preferably a pocket ruler, should have been placed slongsade one of the eggs to indicate its true saze, or a human hand might have been included in the view, picking up one of the eggs or holding it in the palm. The picture was a snapshot at close range, employing a supplementary lens.

CAMERA CROSS ROADS OF THE WORLD

how the camera is operated before we start using it. This department would like to suggest that manufacturers and distributors issue two sets of instructions, one extremely brief and giving only the bare essentials necessary for operating the camera, the other more extended and detailed. The brief one would be for use in the first moments of possession of a new camera and would be written in monosyllabic language, just as one would give instruction to a child. Best of all, the dealer should load the camera for the purchaser, set the distance and stop for fixed focus operation, instruct the user to shoot only in broad daylight, and show him where the release button is After the first roll has been exhausted, the new-camera owner may come to his senses at last and decide to cut out the foolishness and get down to bress tacks

BALANCING THE ANGLE

MEN at work frequently offer striking subject-matter for picture makers, and one of the best viewpoints to adopt for unusual pictures is that of the up-angle. In the present illustration, the men were suitably placed for a good composition. The sary to wait for the standing man to get

"Men at Work"

could truly be said to have balance. This balance is facilitated by the fact that the man's body is slightly tilted forward. Unity is achieved, too, by the fact that both men are engaged on one thing and are facing towards each other. A filter was used for the sky.

THAT DOUBLE CHIN

OCCASIONALLY you will be confronted with the problem of how to minimize or to some extent avoid representing the double chin of your subject. This is particularly a problem with women. In modcrate cases, a shift in the angle of the head is all that will be necessary. Have the subject seated facing on an angle with relation to the camera and then turn her head towards the camera. Caution must be used here, however, to prevent too many folds in the neck, which might prove almost as

"Make Money With Your Camera"

Photo-Markets

This 144-page book tells what to "shoot," how and where. Gives directions for submitting photographs to magazines. Lists hundreds of markets for photographs, together with the types most suitable for each.

Eighth Edition Revised-Up-To-Date 50 Cents, Postpaid

SCIENTIFIC AMERICAN 24 West 40th Street New York City

Profitable Photography with the

Ministure Camera By Edwin C. Buxbaum, A.R.P.S.

BESIDES having a considerminiature camera, making trick "shots," art photographs, and the like, you can also use it for special paying work. This little paper-bound booklet of 72 pages tells not only how to make interesting photographs that are salable to news agencies or magazines but also gives many clues to the very large number of types of photographs that can be sold. For those who wish to mix profit with pleasure this booklet should prove most helpful.-\$1.10 postpaid.

FEARLESS CAMERA CO. 8572 Santa Monica Blvd., Hollywood, California

disturbing as a multiplicity of chins. An up-tilt of the head, often very suitable for women, is another dodge. Another, perhaps more useful procedure, is to light the subject predominantly from a high position so that the minimum light reaches under the clun, by reflection, to show just a trace of printable detail there

PORTRAIT BY CANDLELIGHT

THE flame of a candle at a distance of about two feet from the subject provides sufficient illumination for an exposure of one second, or a little less, at stop 1/35 when using Super XX or Superpau Press film. To minimize slindows on the

"By Candlelight"

face, have the subject face towards tin flame. There is a tendency in this type of picture for the subject to stiffen up unduly as if awaiting some catastrophe. Try to induce the subject to assume a natural. PRSS DOSP

SHUTTER TESTING

AT THE FAIR

AN opportunity to have the shutter of your camera tested the next time you visit the New York World's Fair, is officed by the Universal Camera Corporation They write us.

"A new ingenious device for testing shutters is made available for the first time. This tester, an exclusive Univex engineering development, is designed to test all makes of shutters. Visitors can bring in their own cameras, of any make or manufacture, and have them tested for accuracy of shutter speed. This service is available to anyone and the Univex representatives will be glad to test any camera

No-Border Enlarging

WHEN enlarging on paper with greater dimensions than your easel will take and when it is desired to print without a border, a simple procedure is to pin the four corners to the baseboard in order to prevent slipping or to hold down a paper

it in AMERICAN

that is inclined to curl somewhat. A still easier method and one that will leave the print clear of marks to the very corners, is to use double-sided adhesive. This is available in a product known as Twintak. Cut four short strips, remove the linen fabric that covers one of the adhesive sides, and attach to the under side of each of the four corners of the paper Then place the paper in the desired position on the baseboard. after having previously focused on an ordinary sheet of paper in the usual way, and the paper will stay put wherever placed.

CLEANING OLD PRINTS

HERE is a professional tip that many amateurs can put to good use Onc otographer who occasionally has to revive an old print which has become soiled for one reason or another, does so by the simple expedient of applying a thin paste of ordinary starch to the surface of the print. He allows this paste to dry for about 10 minutes. At the end of this period, he holds it under the tap and removes both starch and dirt by running water over the print.

SOFT DEVELOPER

POR that contrasty subject, with very strong high-lights and deep shadows, we recently came across a developing solution that just about hits the nail on the head. It is called GD-33, is easily made up from familiar chemicals sure to be found on every normally equipped chemical shelf, and is extremely stable. Made up for tray use, the

ormula follows:	
Metol .	75 grains
Sodium Sulfite	1% ounc
Sodium Bisulfite	15 grains
Hydrogunone .	20 grains
Sodium Carbonate	130 grains
Potasium Bromide	15 grains
Water to	32 ounces

ANTON F. BAUMANN

WIDELY known and admired both as W a photographer and a personality, Anton F. Baumann has shot his last picture A victim to the desire for original viewpoints in photography, Baumann, a master of 35mm technique, died while attempting an unusual picture angle.

"He had just completed a lecture and demonstration tour of a number of southern cities," says the announcement of his death, "and was making pictures when he met with an accident in an attempt to obtain a 'different' angle from a high position.

"Anton F. Baumann entered the employ of the firm of Ernst Leitz as a young boy, heing engaged in the research department. realized its possibilities and soon devoted all of his activities to making pictures and lecturing on Leica technique throughout the world. . . . His lectures and demonstrations were a delight to thousands of photography enthusiasts, for they taught them how simple it is to make enlargements from 1 by 11/2 inch negatives. When modern color films first appeared, Baumann immediately saw the possibilities of this new medium and devoted much of his time to it. He projected his slides to audiences throughout the country and inspired many photographers to work with this new medium."

WHAT'S NEW

In Photographic Equipment

If you are interested in any of the items of described below, and cannot find them in our advertising columns or at your photographic dealer, we shall be glad to tell you where you can get them Pirase accampany your request by a stamped envirope.

DUPLICATE TRANSPARENCIES FROM KODA-CHROME: 35mm duplicates, for acreen projection, or enlarged duplicate transpar encies up to 11 by 14 inches from original Kodachromes taken with miniature camera. Also, "same-size," enlarged, or reduced-size duplicates from most sizes of Professional Kodachrome Miniature sizes may he submitted, through dealer, either mounted or unmounted

ILEANY DUTY PHOTO FLOOD "HI-LO" SWITCH: Control switch capable of handling group of two, three, or four lamps drawing total power up to 2400 watts. For ex-smple-four No. 1 lsmps, four No. 2's, two No. 4's plus two No. 1's, and so on. Unit comprises steel box four inches square by two inches high, with toggle switch lever on top and pair of outlets on each of two sides. Finished in nest crackle gray. equipped with rubber-covered, heavy-duty line cord and plug. With switch in "Hi" "Lo" two pairs of outlets are connected in series, dimming illumination, reducing current drain and heating.

TRIPLE S SUPERPAN REVERSIBLE (100-foot length, \$6; 50-foot length, \$3 25): New 16mm motion picture film Rated four times faster than Agia 16mm Superpan Reversible, permitting two lens stops less exposure or corresponding increase in subject range. Speed combined with fine grain and brillient gradation.

LAFAYETTE FILTERS AND MOUNTS: Available in 12 sizes to fit all lens diameters 23 to 42mm. Include light and medium yellow, light green, medium green, and red. Mounts consist of barrel and clamping ring which screws over its outer end to hold filter glass in position. Inner end of barrel slips over lens mount and has spring fingers to insure firm grip. When clamping ring is screwed into place it does not reduce inside dianieter of mount.

WESTON MASTER, Model 715 (\$24): New model featuring separate scales for low brightness range, 1/10 to 50 foot-candles, and high brightness range to 1600 foot-candles. Manufacturers cite example of person sitting near average reading lamp at night reflecting five candles per square foot to indicate extreme sensitivity of low scale. On high brightness side, readings far higher than heretofore are provided with such subjects as heach or snow scen "High Light" scale viewing angle cut to 30 degrees for greater accuracy in measuring central point of interest, without being afrected by surrounding light. Film speed range increased, providing for film speeds from 3 to 800 Weston. More // stop-shuter combinations provided on Master calculator dial. In changing film ratings, touch button and emulsion dial moves smoothly; release and dial locks securely. Hermetically sealed housing around cell keeps moisture out. Streamlined outer case molded to fit hand, with special ribbing to prevent slipping Decorative chromium strip forms secure ribbon eyelet at end.

Speepo Print Dryer, new model (\$14.85).

Dries glossy prints plus regular matte or semi-matte papers. All-metal cabinet, with

crackle finish. Insulated Bakelite handles prevent accidentally burning fingers. Scientifically circulated and

controlled air warmed electrically. Minimum drying time, with full protection against scorching. Capacity: six 8 by 10-inch prints, five 11 by 14-inch, or more than 400 contact prints 1 by 1 1/2-inch, all in one dream.

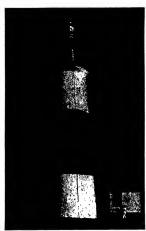

KODAK TRANSPARENCY ENLARGER (\$18.50 for complete outfit, with three filters, special masks for 35mm and "Bantain" frames, and operating instructions) For making enlarged negatives from Kodachrome trans-parencies or black-and-white film positives without using darkroom Accommodates either double-frame (1 by 1 1/2-inch) 35mm film transparencies or No. 828 film Enlarger loads with either Super XX (XX616) or Panatomic X (FX616). Negatives about 2 1/8 by 3 1/8 inches obtained from 35s film and approximately 2 1/4 by 3 5/8 inches from No. 828 frames Operation transparency, mounted or unmounted, positioned in enlarger gate end hinged diffusing-glass cover closed over it. No 1 Photoflood in reflector is held about five inches over gate, end enlarger shutter, op-erating only on "time," is opened for several seconds. About five seconds suffices with transparency of average density, using Super XX film. From enlarged negatives, any number of contact prints or greater culargements may be made.

DUANCOLOR PF CUT FILM (DOX of 6, 42 to 1871 copening on saze, 214 vb 3 1/4 to 8 by 10 inches) Infraorum DATLIGHT TYPE (CUT FILM (price range same as above): New PF type cut film affords greater speed where thirds lable. Primarily intended for whether the property of the film has second at 1/8 yields rich, clean transparences. The color balance of the film has film has filmly developed, accurately recording the simely developed.

LECA, SYNCHINOUIDE PLASH UNIT MORELY (\$28.56); by means of new baseplate, synchronization is effected by mechanism of camera itself. No external synchronizing heads, devices, or connecting wires required. Battery case attached directly to special baseplate of camera by means of dovestield silder which holds it in position. Bulb socket of griding type, Reflector adjustable for two positions depending on bulb sites. Small test lamp, located in neck of lamp socket, each as pilot for effecting

JACOB DESCIIN, conductor of our "Comera Angles" department, will answer in these columns questions of general interest to ametize photographers. If an answer is deviced by mail, enclose a stamped, addressed encelope, Queres should be specific, but MT Descrito cannot undertoke to draw comperisons between manufactured products nor to advise on the purchase of equipment or materials.—The Editor.

Q. Is it possible to change a positive movie film to a negative? If so, how? If you have any information on how to make prints, using movie film, I would appreciate it.—J. K.

A. A positive movie film is used to make a negative by the contact printing method. In our June, 1933, "What's New" column we announced the introduction of the Kodak form enlarger, by which these small movie positives may be directly enlarged on 616 film. The resulting negatives are then used for making contact prints or, if desired, still larger pictures by the enlarging process.

Q. I am thinking of buying another camers. How can I decide what camers and lens will suit my purpose? The pictures I take are distant access and anaphots of interesting objects seen when walking around with the camers. For years I have been interested in ranking color pictures and would like to know if you can give me some information on the subject. How do the Kodachrome, Dufaycolor, and Autochrome processes differ?—M.

A. Portability is probably one of the first considerations in your case. Prece and size of negative are others. If you can allow it, we would suggest the purchase of a cenera that will permit the interchange of the control of the c

As to color photography: This has been implified docky imedra as the production implifier docky imedra as the production implifier docky imedra as the production product ramparencies are concerned. If you plan to do much color photography, the sizes of color film available may have some bearing on your choice of a camera. Kodachrome. Dufaycolor, and Filmcolor (Autochrome, formerly available in platea, has been superseded by Filmcolor in cut-film form but with the Autochrome enulsion) are all similar in the sense that the color secreta and the nunchromatic emulsion have

been combined, so that exposures may be made in the same manner as ordinary black and white film. The color screen faces the and white film. The color screen faces the color of the color

Q. Can you tell me the reason for the vertical line of atain running through the center of certain negatives atored in negative enclosures?— S. F. I.

A. This is a common difficulty experienced by photographers who file negatives in enclosures having a glued or pasted seam down the center The nature of the adhesive, plus moisture, is probably the cause You should use enclosures with an edge seam and file the negatives in a dry place The stain may be removed by hardening the negative in one of the hardening baths, such as the SH-1 Formalin Hardener, and then placing the negative in a 1 or 2 percent solution of potassium cyanide until the stain disappears. Cyanide being a deadly poison, make sure the room is well ventilated and, after use, discard the solution down the drain only after having made sure that there is no acid in the sink or trap-

Q. I desire information on the use of powder for flashlight photography. Would you say that its use is the answer to getting flashlight action above to getting flashlight action above hubbs are positive, give no anode, and so on, but outside of that would the use of powder be just as good? Flease describe the technique of using powder satisfactorijy—H. B. B.

A. Flash powder today is used almost exclusively by newspaper and commercial photographers when it is required to cover a large area, particularly outdoors at night. The low cost of flash powder as compared with that of flash bulbs is greatly offset by the disadvantages of the former. The immediate swing to flash by both amediate swing to flash bulb to the disadvantages.

teur and professional photographers as soon as these became available is a certain indication that the higher cost of the bulbs has proved no drawback to widespread ac-

From your query we gather that you are sware of the main advantages of the bulb over the powder, so we won't dwell on them You probably also know that smallsize bulbs, proportionately lower in cost than the larger ones, will provide sufficient illumination at normal distances to give well-exposed negatives at small stops our opinion, chespness is the only advantage that powder has to offer over the bulb, for average working conditions Mention must be made of the hazard attending the use of powder-that of untimely explosion Special care must be used both in storing and igniting powder Flash powder is fired in a device known as a flash-pan, provided with some automatic method of ignition. The powder must lie exposed and not confined in a container of any sort A brief flash is obtained when powder is heaped in one spot, a longer flash when the powder is spread over the pan, thus insuring the maximum of light Instructions are supplied with each container of

- Q. Since I do not own a scale with which to weigh chemicals when mixing developer, can you tell me how to measure out chemicals, using tableapoon measurement?—F. H. J.
- We would if we could but we can't The fact is, chemicals vary in weight and so would necessitate a different table of measurements for different chemicals. While the weighing of chemicals for the compounding of photographic solutions does not always have to be critically accurate, the use of a tablespoon system of measurement would be stretching the point a little too far. By employing one of those vari-sized spoon sets used in weighing out cooking recines, it is altogether possible to figure out a method for preparing formulas, but a weighing scale would be necessary to fix the quantities. Scales are not expensive and sometimes may be nicked un second hand for much less than their original cost. In this connection, the dollar Weigh-Spoon device mentioned in our "What's New" column some time ago should be suitable. If you employ standard developer formulas, these, as you probably know, are available ready prepared in dry form, requiring merely a stated quantity of water to make them ready for use. One manufacturer solved the problem you have in mind by providing wooden measures in each package of chemicals. These are sold under the name of "Mak-a-tube" (de-veloper), "Mak-a-fix" (fixer), and so on.
- Q. What causes a partial reversal of the negative image in the course of development?—P. R.
- A. The reason may lie in fogging caused by the use of an unsafe light in the darkroom or in extreme over-exposure while in the camera. Another cause is the use of an oxidized developer.
- Q. I write music as a vocation and follow photography as a hobby. When I receive an order, for, say, 50 copies of the same piece of music, I would like to be able to make the first copy by hand and from that reproduce the

other 49 copies with the camera. Can you tell me how I can photographically copy music on both sides of the

same sheet of paper?—H. K. J.

A. Aside from the method of individually sensitizing each side of the paper, you can employ a double-coated paper expressly made for the purpose you have in mind However, because there is so little demand for this kind of paper, it will be necessary for you to purchase a fairly large quantity. But since moderate quantity reproduction is required, this should offer no problem. We understand that a paper of this type, sold in large rolls, is obtainable from the Gevaert Company of America, 423 West 55th Street, New York City The company will cut the paper up into the sizes you specify We would suggest that you write to the company and state your problem, making clear your requirements, which will include the facts that the paper must be non-glossy and thin and flexible enough to permit folding without cracking

- Q. What do I have to do in order to print on special cards some of the pictures which I have taken?—Mrs. C. W. R.
- A. The first step is to convert the cardinto regular photographic paper by sensitizing them according to the formula given in our reply to E. W. D. in the September, 1938, ssaue. When that has been done the rest of the procedure will be similar to that employed in the contact printing routine.
- Q. My No. 1 Auto Self-Timer exerts, in my opinion, a very great pressure, so great that I am afraid to use it lest it shall break or bend the tiny trip bar located under the cable release socket. Please advise if there is any danger of damaging the shutter in this manner. —A. K. B.
- A The pressure you refer to is necessitated by the nature of the timer's design, but will do no harm to the shutter. There is no adjustment on the No. 1 timer for the pressure required to set up the delay mechanism, as there is on the No. 2 timer You can, however, feel secure in using this timer without danger of damage
- Q. How can I enlarge from a wet negative?—R. L.
- A. Make a glyceruse "andwich" beveen two pieces of clear glass. Apply a little glyceruse in the center of one glass. Apply a little glyceruse in the center of one glass, the west negative on it and apply another drop on top of the negative. Place the other glass on top of the negative. When sand-wiched together, the glycerine will spread, overring the entire negative and thus preventing premature drying of the negative while being projected in the enlarger.
- Q. What is a good way to copy a photograph made on a matte surface —L. D. G.
- A. In order to overcome the disadvantage of the matter effect for copying purposes, and to help bring out shadow dotail, mamerse the print in water, let a took a while, and then lay it face down on a sheet, of plain glass. Squegee at down firmly until all bubbles and air pockets have disspeared. Make sure the glass is clean before you lay down the print. Face the print, through it glass "cover," towards the camera, and light it evenly by using two light sources of equal intensity, one on each side.

PHOTOCHEMISTRY AND THE MECHA NISM OF CHEMICAL REACTIONS

By Gerhard K Rollejson and Milton Burton

I has long been known that light plays as unportant part in creatin chanucal processes. Only recently, box-ever, have such processes been studied estemately and photochemistry made a tool for the study of the detailed mechanisms of reactions. The authors of this volume, while maining a critical attitude, have endeavord to present the subject so that the read-ever will not only understand its background.

We can supply our readers with any of the books reviewed in this department. Prices quoted include domestic postage. Foreign prices are necessarily higher due to increased shipping charges.

SCIENTIFIC AMERICAN 24 West 40th Street New York, N. Y. but also realize its possibilities. Approximately one third of the book is given to presentation of the fundamental concepts required for an understanding of the effects produced by the absorption of light and the behavior of the reactive states produced in this manner. The remainder is devoted to specific reactions which can, in part, be regarded as supplementary material for the earlier chapters. Many original references are given, nine pages of appendixes, 17 pages of subject and author indexes (445 pages, 6 hy 9 inches, 59 diagrams) -\$5.85 postpaid L B P

SILK SCREEN STENCIL CRAFT AS A HOBBY

Ry J I Biegeleisen

A HOBBY that anyone man, woman, or child can follow with enjoyment and even profit is offered in this clearly presented book Lamp shades, table cloths, greeting cards, invitations, program envers. and a multitude of other things can be produced in colorful designs, singly or in quantily, by the easily mastered silk screen stea of process. The author gives all needed instructions and has amplified the text with a number of pertinent drawings and photo graphs (140 pages, 6 by 9 inches, 39 il-Instrutions) \$2.10 postpard A P P

AMERICANS.

By Fmil L Jordan

SERIATIM, the author gives separate bistorical narrative accounts of the soutribution of each racial and national stock to the New World Indian, Viking, Spanish, Portuguese, French, Dutch, Brit ish, Negro, Chinese, German, Irish, Scan dinavian, Slavic, Italian, Jewish thus en abling the reader to judge which stocks have contributed the most. This is no dryas-dust lustory but is eminently readable, your reviewer forgot he was reading for review. The style is preponderantly narrative and necasionably a bit spicy (459 pages, 5 1/2 by 8 1/2 inches, 8 illustrations) -\$3 60 postpaid -- A G I

CHEMICAL PIONEERS

By Williams Havnes

N the details of their accomplishments, the story of these 15 builders of progress is of great interest to its today; their constructions have become our great chemical industries (288 pages, 5 1/2 by 8 inches, 58 illustrations, index.) -\$2.60 postpaid L B. P

MAN AND HIS LIFE-BELTS

By E. T. Bell

YNICS will enjoy this book Beil is a A noted science teacher who has written other cynical but penetrative books, using a sharp pen. He is aggravating, irreverent, iconoclastic, skeptical, enjoyable (unless the reader were a conformist, in which case the effect would be most irritating) and always witty. The "life-belts" are govern-ment, scientific invention, economic science and religion (of which he disposes). He says: "The happiest people today are those who know nothing." This sounds true. who know nothing." This sounds true, anyway! (340 pages, 5 3/4 by 8 1/2 inches) -- \$3.10 postpaid. -- A. G. I.

TELESCOPTICS

A Monthly Department for the Amateur Telescope Maker Conducted by ALBERT G. INGALLS

S O far as your scribe recalls, the 30" reflecting telescope described below is the largest yet made by any amateur since this journal revived the art of amateur telescope making 13 years ago J. H. Hindle, of Witton, Blackburn, Lancashre, England, built it and, when invited to describe it, wrote the following.

"THE mirror is a Chance disk, 3 1/2" thick, with a focal length if 120". The aperture is 30" (f/4). It is floated on a system of triangular supports, contacting the underside of the mirror at 18 points.

Figure 1: Cross-section of the cell

l Hindle's well-known system, described in the book 'Amateur Telescope Making,' page 229.—Ed l. A cross-section of the mirror cell, with reference to the edge support, is shown in Figure 1. The annular ring,

"The tube is constructed from solid-drawn steel conduit, such as is used for electrical

for the extraction of the mirror.

Figure 2: The tube construction

wiring purposes, and the lengths are threaded through circular rings of heatrested, high tensile slumnum alloy. These rings are securely clamped to each tube by means of a taper fitting such as is used for attaching ball bearings to a straight shaft (Figure 2). The diagonal bracing is of high tensile steel wire, which is pulled taut by means of screws at the bottom end of each tube, near the mirror moont. A perfectly rigid tube of minimum weight is thus obtained

"The four arms of the spider carrying the diagonal are of phosphor bronze sheet, mounted on the extreme end ring, with provision for concentric adjustment.

"The diagonal mirror is 7" minor axis, and about 1 1/2" thick, mounted in an alumnum and brass cell which has a tubular stem, so that electrical means of slightly rassing the temperature of the back side of the plane, to avoid dewing, can be adopted, as described in 'ATMA' by Dr. Steavenon.

"The pumary mrow is not perforated. It is collimated with reference to the brass sleeve which forms the center of the spider, returning its reflection precisely concentre with a ground spot, exactly in the center of the mirror itself. The expelce support can be readily detached from the tube in necessary, and there is a considerable necessary, and there is a considerable supported at three points, the final set is a supported at three points, the final set is the property of the property o

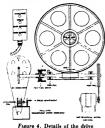

"The polar axis is built from a 5" steel tube, with 1" thick walls, and the ends plugged solid. It is supported in ball bearings, one immediately below the fork, and the other immediately below the worm wheel. The general design of the mount

Figure 3: The nearly completed telescope erected in Hindle's plant (Union Engineering Works)

for a latitude of \$1.1/2* is clearly seen from Figure \$2\$, the fort isself being a substantial iron casting of 'U' section, split where it also on the top of the boler aris, to which it is firmly attached by compress on bolts. A segment of a worm wheel on the trunnion of the tube enables the electope to be adjusted in declination, through the medium of a worm and spur gear, with a featile joint to a brown handle

within reach of the observer. When the

inclined steel handle and its nut are relessed, the tube can be moved to any approximate position by hand

"The drive to the polar axis is possibly to some extent novel The worm wheel on the polar axis is definitely fixed to it, the usual clutch being dispensed with. That enables the wheel itself to be more precisely mounted, and the engagement of the worm and wheel more definitely adjusted The primary drive is by gramophone motor, through a 60-to-1 worm gear, which, in turn, through a friction drive, rotates the main worm shaft and the wheel on the polar axis, the latter reduction being 360to-1 (Figure 4). Particular attention is directed to the small worm gear, which is carefully assembled and runs in ball journals to reduce friction to a minimum, so that the gramophone motor is not overloaded. The pitch of worm and wheel is 10 D.P., that is π/10, and the pitch-circle diameter of the worm is 0.75", so that the angle of the thread is 7 1/2", which practically gives irreversibility. The compression springs on the friction drive enable the necessary power, with an ample margin, to be transmitted to the main worm shaft.

"The gramophone motor is to be independently mounted so that no vibration or electrical hum can be transmitted to the electorope. At a speed of about 60 r.p.m. the normal speed of the polar axis is secured, and this is capable of permanent and delicate adjustment. Energizing a small A.C. electro-magnet entirely releases the brake on the governor of the motor, and allows it to run at top speed. This occurs when the accelerating button is depressed, the property of the control of the control of the property of the control of the control of the property of the control of the control of the property of the control of the control of the property of the control of the control of the gramophone motor circuit, allowing the oblect to overstake the telescope.

"Rapid adjustment in right ascenaion is effected by means of a separate 1/4 h.p. motor, which runs in either direction as desired. Due to the greater power of this motor, the friction drive loses control, and

THE BEGINNER'S CORNER

RIPODS instead of fixed pedestals are TRIPODS instead of fixed possessions of first desirable in many instances for first telescopes, because first telescopes usually are small enough to be portable Light, flursy tripods, however, are too shaky for a telescope, because the telescope magnifies

solid, he-man tripod should be built, in stead of the too common "pansy frail" Give it good hisky legs. Usually, however, you will want it portable, but its length will defeat this unless you make it jointed-and then comes the question of a joint that won't, in turn, defeat the effort to make it rigid.

One kind of folding legs is shown in the accompanying photographs of a tripod made by F. M. Garland, 1006 Davis Ave., Pittsburgh, Pa. These fold outward and upward,

rather than inward, and thus nest closes when folded The tripod has three hinged central braces in addition, made of strap metal slotted for adjustment and provided with a wingnut for tightening braces are far enough above the knee joints of the legs so that they will not extend be

low the latter when the tripod is folded Main feature of Garland's tripod is the knee-joint which, once locked, is as solid as a human knee in a plaster cast. On the outer not the inner-side of each log i a heavy backflap hinge, as shown in the lefthand closeup, and on the inner sides are metal straps pivoted at their tops on a screw and side slotted near their bottoms. Each slot has a bolt and wingnut for tightening

Other stiffening and strengthening details show in the photographs. The tripod shown weighs about 15 pounds and is very rigid The refractor seen on it is an old 3 1/2" Brashear

TELESCOPTICS

(Continued from preceding page)

the reder axis makes a complete revolutron in about a minute. Owing to the limitation of power that can be transmitted by the friction drive, and the practical preversibility of the small worm gear, the graniophone motor is quite unaffected by the rapid adjustment taking place, and continues to run on as usual limmediately, therefore, after the 1/4 hp motor is disconnected, the friction drive instantly resumes its functions without any lag or loss of time whatever During normal working, the 1/4 h p motor rotates tells, very slowly

This ends Hindle's description Readers of "ATM" and "ATMA" will recognize him as a co author of those books By vocation he is a manufacturer of loomsthose very heavy ones of 30 tons or so such as are used in weaving the dryer felts of cotton, thick and wide, used by papermakers. The same readers will recall the picture of a 30" mirror on a granding machine, on page 245 of "ATM" (fourth edition of 1935), this is the same mirror Hindle enjoys making telescopes Having made them, he gives them away! However, lest about 10,000 readers obey that impulse to rush applications for free 30° reflectors by cable, we hasten to add that he hasn't exactly given away his two large telescopes, a previous 20 1/2" and this 30", in quite that way. He has, however, commendably arranged to place them where they will work hard for astronomy. The 20 1/2" (see its photo in "ATM," page 153) has been in the hands of Dr. W Steavenson, a pronunent English variable star observer, more wolchy known by hundreds of astronomical friends in Britain end America as "Steave," who contributed the chapter on dewing of optical surfaces, in "ATMA" The new 30" is being mounted in the grounds at Cambridge University Observatory by arrangement with Sir Arthur Eddington, where it will be available for the use of the Professor's staff Later Dr. Steavenson hopes to be in a position to make regular use of the newer instrument himself

LAST month in this department there was a long article by Hendrix and Christie, of the Mt Wilson Observatory, on the Schmidt camera, and now we have the following comments on that article written by Prof C H Smiley, Director of the Ladd Observatory at Brown University and a leading exponent of the Schmidt camera;

"It is with some hesitancy and considerable distaste for the task that this criticism of the article by Hendrix and Christie in last month's Scientific American is written. I am deeply indebted to Mr. A. H. Joy of the Mt, Wilson Observatory and to leave retent to Mr. Hendrix for valuable asstance and advice in 1937 in connection with improvements made on the Ladd Observatory Schmidt camera which had just been completed. I am well aware that Mr. Hendrix has made more Schmidt camera, that any one else on earth. If I were asked where the outstanding authorities in astronomical optical work were located, Mt. Wilson Observatory and Hendrix and Christie would come first to my mind

"Even so, one of the sentences early in the article by Headrix and Christin seems to me to be distinctly inflate." "several arnicles have been written about the 'chimid camera since the unventor set forth arprinciples in 1843, but little that in new principles in 1843, but little that in new hard that it is not a series of the series of the table that is not a series of the series of the internal series of the series of the series of give a multi-maried design for the correcting plate, he did not give any method of testing nor was his method of mixing a correcting plate revealed to the public mixing the series of the rese lives been used out of the series of the F B Wright, B Strongren, H \ Lower, Y \text{ Lower, Y

"One might overbook a single ingenerous remark in the early part of the article but a considerable amount of material presented in the latter part of the article has previously been published by others, yet the article does not indicate this. A recent letter from Christie suggests that Hendrix and he knew all these things before others published them I do not question the vit acity of this statement. However, priority in scientific matters is usually established by publication in a journal generally avail able to others. On this basis, F. B. Wright and B Stromgren should receive credit for their publication of the matternatical design of the correcting plate, and other acknowledgments of priority in publication should have been made

"In brief, I feel that the ingenerous and moderating statement concerning carba." In brief, I feel that the innermon the publications and the failure to mention the publications and the failure to mention the statement of the publication of the interest of the past five years and have withheld it from publication during that interest.

RULE for finding sagitta of a mirror, expressed directly in sixteenths of an inch, offered by Joseph Dwight, Hvaimis, Mass Divide aperture by focal ratio.

To measure depth of sagitta on a mirror while roughing out, Lloyd Anderson, 11909 Vicenie Blivd, West Los Angeles, Cahi, pius a small drop of soft pitch at the center and places a sivel sizight-redge across the mirror, pressing the pitch down Then, with thickness of the pitch. Automatic feeler?

TRADE MARKS AND UNFAIR

COMPETITION By ORSON D. MUNN

A TRADE MARK is an intangible asset of a business, yet its actual value may grow so large that it becomes the very foundation on which depends the whole attructure of the business. Because of this fact, every business man should have available such information on trade marks as will enable him to judge with a fair degree of accuracy the desirability of any mark which he may be considering.

Here, in one handy volume, written in non-legal terms, is a simple yet comprehensive interpretation of the Federal statutes and the body of common law relating to trade marks and unfair competition

CURRENT BUILDING BRILDS

(The Editor will appreciate it if you will mention Scientific American when writing for any of the publications listed below.)

TRAINVION CYCLOPERIA, compiled by M. N. Bettman, a a pocket-sure boddet which will brang the reader amparely up-to-date the property of the property of the property of the property illustrated with drawings and photographs, it covers the entire field from "Abertation" to "Work Function" as appendix puts for the fundamental principle, of television as a running story, interestingly told Scenarize American Book Department, 24 West 40th Street, New York City.—50 creats.

New Houszons or Industry Tranductor Richards in a Galpage bookler that presents "a tour through the present into the future" it covers scentific research and its applications in industry throughout a bread field tranging from automobiles and chemical through health and homes to rosds, rubber, vision, and wood. It is essentially a high-lighted survey of what will be accomplished in the future, based upon accomplishments in the future, based upon accomplishments in the future, based upon accomplishments for the future of the futur

METALLIZING HANDBOOK is a 26-page booklet which gives complete details on metal spraying, together with a series of pictures which shows specific applications. The equipment necessary for such work is listed. Metallizing Company of America Inc., 562 West Washington Boulevard, Chicago, Illinois - Craits.

TYPICAL NICKEL ALIOY STRAIS AND CAST IRONS EMPLOYED IN DUSSE. CONSTRUCTION is a single sheet tabulation which covers these metals as used in light, medium, and heavy Diesel eigines. It tabulates engine parts, recommended compositions, mechanical properties, and best treatment. The International Nickel Company, 67 Wall Street, New York City.—Gratis.

THE INDUSTRIAL USES OF PRISTO SOUND RECOGNING EQUIPMENT is a 12-page pamphlet, illustrated with a number of photographs, which describes this type of high-tographs, which describes the type of high-tographs, which describes the type of high-tographs, which describes the type of the

SEALAIR Winoows is a 10-page, completely illustrated booklet which shows and describes all-alumnaum windows in stock and standard sizes it should be of particular interest to the bome owner who is considering building or rebuilding. The Kauncer Company, Nules, Michigan—Gratis

Practical Television by RCA is a 40-page book which is particularly concerned with circuit design, antenna installation, and reception. It is published for service men, dealers, schools, and anyone interested in a survey of television as it stands today. It presents a general discussion, technical description of receiving circuits, details of television receivers, a section devoted to general service problems, and a group of television definitions. Obtainable from RCA distributors or direct from RCA damalgacturing Company, Camden, New Jussey.—25 cents.

New Photography Recome is a stemgraphic report of the second annual short course in news photography at Kent State University. It covers, in lecture form, practically the entire field of photography, from the lastest developments in cameras and equipment to color photography, photography and the professor of Journalism, Kent State University, Kent, Ohio.—425.8

DYES is a 12-page illustrated booklet which has been prepared to correct certain misconceptions. It clarifies, for example, the suitation as regards the dependability of American dyeatuffs and the identification of color-fast mechanidae. It also relis of the research which is being extraed on to accome the Americanidae of the property of the color of the

ALLID'S RAPO BULDEN's HADDROOK is a 30 page, thoroughly illustrated booklet which gives the reader some theoretical background, together with a knowledge of rado circuits. A short section is also devoted to anateur radio—how to operate matteur radio—how to operate matteur radio—how to operate received in the received of the received to anateur radio—and the received in code. A group of circuit discrepance of the reader something concrete to work on. Allied Radio Corporation, Serves Jackson Boulevard, Chicago, Illinois.

AN ADDRESS BY EDWARD G. BUDD 18 a short, compact reprint which gives a brief but thorough survey of railroad travel in the United States as it is today. It gives a better over-all idea of how the railroad putter has changed within the last few years than could be obtained from many a long-winded technical discussion. Edward G. Budd Manujacturing Company, Philadel-phia, Penaryleum,—10 cents.

PRILIPPINE MUNICY FLAR BOOK contains a complete history of the varrous maning dustricts in the Islands, the history of the heads producers, and a review of the base producers, and a review of the base representations of the producers of the producers of companies, mines, personnel, and results obtained Ralph Keeley. Post Office Box 769, Manila, Philippine Islands.—11.09.

This American Way in Industrial Research is an 8-page illustrated reprint which describes specifically the work of Mellon Institute and other institutions which are today shaping our industrial future by the work which they are doing in various fields of research. Mellon Institute of Industrial Research, Pittsburgh, Pepasylvania.—Gratis.

Patent, Trade Mark, and Related Legal Proceedings That May Have a Direct Effect on Your Business

By ORSON D. MUNN, Litt.B., L.L.B., Sc.D.

New York Bar Editor Scientific American

BATTLE OF BATHS

WO bath preparations similar to bath Two bath preparations summer, were salts, both bearing French names, were involved in a recent suit for unfair competition and trade-mark infringement. The manufacturer of a bath preparation bearing the trade mark "Bain de Champagne" brought sint against a competitor selling a bath preparation under the name "Bain Mousseux charging that the names were confusingly similar to each other It was pointed out that the word "Bain" meant bath and that accordingly the plaintiff's trade mark meant bath of champagne whereas the defendant's trade mark meant sparkling bath The defendant's preparation when added to the water in a bath conveyed a sparkling or effer-vescent character thereto. The plaintiff contended that the word "sparkling" used in the gest champagne and for that reason the defendant's name would necessarily be confused with plaintiff's.

The court, however, pointed out that in sound and appearance the two names were quite different and that furthermore the word sparking suggested many other products be-aides champagne. Since the defendant's name was merely descriptive of one of the characteristics of the preparation the court refused to restrain the use thereof.

CHORUS

THIOSE of us who have difficulty in remembering more than the chorus of a song and find ourselves humming or singing the chorus of a song over and over again will receive a certain amount of moral sustenance from the judicial declaration that the chorus forms a substantial portion of a ment the owner of the copyrights on two songs charged that a printing company was sulty of copyragin infringement because it

had sold printed copies of the choruses.
One of the defenses raised was that one of the mere copying of the choruses did not constitute an infringement of the copyrights because the choruses did not constitute substantial and material parts of the songs. The Court held that this defense was without mert, stating.

"The chorus of a musical composition may constitute a material and substantial part of the work and it is frequently the very part that makes it popular and valuable."

TURN AROUND

IN a recent decision of a Federal Court
the trade mark Run-R-Stop was held to
be infringed by the trade mark Stop-A-Run.
In the suit is question the manufacturer of

a find to be used in stopping runs in all, assockings charged a competition, making a similar product, with unfair competition and trade-mark infringement. The Court found that the planniff had used its trade mark Run-R-Stop for many years, had spent a great deal of more join advertising, and deathy established a secondary of the purchasing public that the product was manufactured by the planniff.

manusctured by the plantin.

The Court recognized the differences between the two names but came to the conclusion that, due to the euphonous similarity between them and due to the further fact that the packaging and dressing of the two products were very similar, the use of the name Stop-ARun by defendant was likely to lead to confusion and constituted trade-mark infunsement.

ADDENDUM AND

DEDENDUM

THE Court of Customs and Patent App peals has allowed a patent on toothed gearing in which the teeth of the driving pinon are all-addendum and the teeth of the driven wheel are all-defendum and with a pressure angle lying hetween 22% degrees and 30 degrees. The terms addendum as and decindum as applied to gearing means that the treth are outside and made respectively correles passing through the pinth point of the pitch erroles. The pitch point of the pitch erroles. The pitch point of the pitch errole are circles passing through the pitch point of the pitch errole. The pitch which are coastale with the area thereof.

The Patent Office had refused to allow the patent on the grounds that the provision of pinnons in which the teeth were all-adendum or all-defendum was old and that the pressure angle of the teeth was more ries optional. On appeal the Court of Customs and Patent Appeals reversed the Patent Office and held that the pressure and produced new results which were not attituded by the patent office and the patent office attitude to the produced new results which were not attituded by rior to the inventors.

In reaching its decision the Court was influenced by the affidavits of several experts who told of the many years of expermentation required to develop the gearing and also stated that the particular angles referred to were critical.

JEWELLED SHROUD

THE utility of a design has no bearing upon the validity of a design patent This principle of patent law is illustrated by a recent suit for infringement of a design patent for an automobile exhaust

Briefly stated, the design patent related

to an exhaust through having a aloping too surface in which a glass reflector; pred was mounted so that the headlights of a car approaching from the rear would be reflected by the swell After considering the elements of the design or appearance of the shroud and finding that they were of more or less conventional character the court hardly considered the utility or function of court pointed to that the surface of the surfa

"Moreover, we must keep in mind that the utility of the combination of the glass jewel and the exhaust shroud is not involved. Utility plays no part in determining the validity of a design patent."

PROFESSIONAL

MISREPRESENTATION

A RATHER novel defense was raised in a recreat proceedings hrough by the Federal Trade Commission against a manuacturer of a soap and outnemn used in the treatment of skin duesses. The Federal Trade Commission charged that the manufacturer was guilty of unfair methods of competition because of mareprecentations appearing in certain of the advertisement of the adve

One of the defenses raised by the manufacturer was that the adventuements in question appeared in a professional journal and that the physicians who read the journal would not be misled due to their medical knowledge A. Federal Circuit Court of Appeals rejected his defense on the grounds that if the adventuements were false and misleading it was immaterial whether and on plus final readers were actually misled on plus final readers were actually misled

The Court also stated:

"Conceding the somewhat violent assumption that prospective patients never read medical and nursing journals, we do not concede either the ethics or the law of a proposition which puts a premium on a failure in wickedness."

B. O.

RATHER intunate and personal issues were considered by the Patient Office tribunals as a recent opposition by a prior-inent soap manufacturer against the application of the patient of th

The Court found that the soap manufacturer would be damaged by the registration of the trade mark "Nohio" and refused to permit the registration, stating:

"Il is evident, we think, that, although the terms 'Nobio' and 'B. O.' do not look exactive alike, the term 'Nobio' and be pronounced as though it were spelled 'No-B-O'; that appellee intended that its term 'Nobio' should he understood as meaning 'no B. O' (no body odor), and that it will he so understood hy the purchasing public."

Industry Accepts

....THE ONLY National Publication to show a consistent FIVE-YEAR GAIN in Advertising Linage. 20% GAIN IN 1939 OVER 1938!

Dependence follows quickly upon acceptance and Scientific American, because of its exhaustive treatment of industrial research, has won the acceptance of leaders of American industry.

Not content with merely reporting the news of the frontiers of research and invention, Scientific American long ago began showing industrial leaders how to apply the new developments from those frontiers to today's procedure.

And in today's procedure, Scientific American plays a definite part. Industry depends upon this publication to bring it the guiding facts that lead to the purchase of the products advertised in Scientific American pages.

Build your sales upon this dependence. Know that your selling facts are read by the men who do the buying, in the publication that impels their buying interest.

Ask us to show you copies of the letters received from American industrial leaders seeking buying guidance from Scientific American.

SCHEMINSON AMERICAN, October, 1939. Vol. 10, 104 a makered at the New York, N. Y. Pest Office as second class matter June 28, 1979 under the set of Manch Per. 1979, additional entry at New Setsers, Come Profitable 1939 by Manch 1979, and the Setsers of the Sets

50 Years Ago in . . .

(Condensed From Issues of October, 1889)

MAINE—"The steel cruser Maine, in course of construction at the Brooklyn Navy Yard, is now in skeleton condition, most of the frames being up. When completed she will be the largest vessel ever built for the United States Navy, being of 6648 tons displacement. The mammoth shed where the work is in progress was erected

during the Civil War Doubtless, to its constructions, the dimensions of this shed seemed sufficient for the longest craft that was likely to he built. Yet the prow of the Maine, with its steel ram and spur, extends many yards into the open. Inside this shed nearly three hundred men are now at work."

BENDING - "The largest bending rolls that the Niles

Tool Works are now building for the Mare Island Navy Yard, San Francisco, possess very interesting features. This machine will bean mild steel plates 2 in. thick by 22 ft wide. It is guaranteed to bend armor plate 1½ in. thick by 22 ft wide. The work is done by four forged rollers, two in the center, stranged one vertically over the other, to grap the sheet between them, and one on either side of the center to hend the sheet."

FLOOD.—"During the Conemaugh flood, thurty-two locomotives, some of them weighing 91,640 lbs., were tossed about like corks, 23 of them being conveyed an average distance of 1347 feet down stream, one soung 4844 feet, the shortest trip being 480 feet."

PARCELS POST—"In June last the Postmaster-General submitted to the Chillian minister the draught of a convention between the republic of Chile and the United States for the establishment of a parcels post system and a postal money order system between the two nations."

TRANSANDINE RAILWAY.—"The Andes are being crossed at the Uspallate or Cumbre Pass, where there will he a tunnel \$\text{SI}\$ mules in length, at an elevation of 10,450 ft. above sea level. The pass itself is nearly 3000 feet higher, or at 13,015 ft. and is situated 4½ miles south of Aconcagua and 334 miles north of Tupungato, in 33 degrees \$\text{S}\$ lattude. It will thus he seen that the ummut level of the Transandine Railway is far above any European lines, which at the Rigi reach to 5753 ft., and at the \$\text{S}\$ Cothard 3786 ft."

WAGES.—"Some paper has natted the nilly question, 'Do Inventions Decrease Wages?' Certainly they do not. On the contrary, mentions increase wages, shorten the work day, and decrease prices. In fact, inventions constitute the only possible way by which labor can be emancipated from drudgery, long hours, and poor pay. Inventions are increasing every year, and wages are contently advancing in all countries where they are utilited."

YELLOW FEVER—"D: George M. Sternberg, surgeon in the United States Army, has past returned from a ax month; any in Cuba, where he has been continuing his researches with reference in yellow fever. He has brought with him specimens of microbes, with which he will continue his investigations during the winter at the Johns Hopkine University.

PHONOGRAPH—"in reply to numerous inquiries we can only say the phonograph has not yet been reduced to that simplicity and perfection of operation necessary for its general sale and introduction. It is true, several examples have been produced which are in use, and many interesting experiments have been made.

But in most cases, in order to get really assistatency recalls, we believe in needs the employment of an expert to watch, adjust, and work the instruments We are informed the machine has recently been improved to as to dispense with all adjustments, thereby rendering it entirely automents, thereby rendering it entirely automation of the property of the property reached this stage of simplicity and prereached this stage of simplicity and prefection, we predict for it a bright future."

WHEELS—"Carriage manufacturers are predicting that in the not distant future wooden wheels will be done away with,

wooden wheels will be done away with, and steel wheels substituted, on account of the increasing scarcity of lumber for wheels."

CRUISER SPEED.—"Advices from San Francisco state that the calculations regarding the horse power speed developed by the cruser Charleson, just completed by the trial board, show a maximum horse power of 7093 and an average horse power of 6816 for four hours, average speed, 18.75 knots, though a maximum of 19½ knots was developed for a short time."

DANGER.—'The most currous protest against railways ... was that drawn up by the Royal College of Bavarnan Doctors, recently discovered in the archives of the Numberg Railways at Furth, the text German line constructed. It contains the following passage, ponting out the danger of the new system of travel: Travel in carriages drawn by a locomotive ought to be forbidden in the interest of public health. The rapid movement cannot fail to produce among the passengers the mental affection known as

DRILL—"An interesting electrical machine can be seen in operation on the framework of the new warning Maine, in the Brooklyn Nay Yard. It is a drill Instead of the slow and tedious pawl and ratchet hand drill commonly used, is one that is set a-whiting by an electrical current sent through carefully insulated wires. A three-quarter inch hole in a three-quarter inch plate can be drilled in less than a minute."

OUR POINT OF VIEW

Co-operation

HOPE for a future of asfer motoring, and for longer lives for embers of the motoring public, may be gleaned from three articles in the present number. First is "Insanity at the Wheel." on page 199, econd is "Self-Contained Unit Headlight," and third is "Motoring Eye Health for 1940." the last two appearing in the Digest section. It does not take much reading between the lines to realize that here are examples of the section of the sectio

With psychiatry bending commendable efforts toward weeding out the unfit among drivers (we hope this will continue on an ever-ganding scale), the electrical industry directing research toward better and safer lighting for motor cars, and the glass companier developing better and safer safety glass for windshields and car windows, we find many reasons to believe that the death toll on the highways, reduced in 1938, will be still further reduced during 1939 and 1940.

Now, if more and more drivers will only awaken to a realization of what is being done to protect them squant themselves and will contribute their share to the co-operative effort, we can really get somewhere in the matter of highway asfety. Naive though it may seem at first blush, it is nevertheless a fundamental truth of motoring that individual applications of the Golden Rule to the rules of the road will go a long way toward making for safer and happier driving —A. P. P.

Pan-American Trade

TRADE with Mexico and consultation of the South America looms large in the thoughts of some of this country's commercial interests. Partly, there is the profit motive but more important is the item of self defense. Freer intercourse between the peoples of the Americas. more enlightened good-will and mutual respect, and an equable exchange of goods and services, all will assist in stemming the tide of foreign ideologies which threaten the peace and independence of several of our southern neighbors. The less this hemisphere is dependent upon nations of other parts of the world, the less likely there is to be coercron-economic, political, and socialfrom those quarters.

Yet despite the need for closer cooperation so that our export-import

T. Hart Anderson

RICHNESS of achievement marked the life of T. Hart Anderson, nationally known pate on lawyer and director of vicinities American, who passed owly at his hart care of the control of the c

"Judge" Anderson's genial smile will long jive in the memories of his friends and associates. Many will, indeed, contame to try to emulate him, for he had astained that precious friendly calmines, so rare in these raibing times, that remains unraffied by the diffairs of little men. Posessed of a judge-like dignily and a superior knowledge of law—specially of that pertaining to expectally of that pertaining to expect all which the pertaining to expect all which the pertaining to grow the pertain of the men and dedicated on the expect and the

His gentle manner, coupled with his many successes in significant litigation, suggest as an epitaph for him the old Latin phrase of lawyers "Suaviter in mode, fortiter in re."

problems might be solved, there are those who blandly refuse to open their minds to logic. Notorous is the hatred some South Americans have for the United States. This attitude, however, is understandable—and curable, too, if it is properly attacked, vigorously and with open minds and sympathetic hearts. But those who despose all Norte Americanos fall far short of being as stupid as some in this country who wish to increase their export business. These are the ones who, with important export products, never, or half-heartedly, attempt to get the prospective buyer's viewpoint.

Many American companies think that they can get foreign bissiness by the same tactics with which they get it at home. They believe the star safesman in the States can get volumes of bissiness abroad whether he knows the language, habits and customs, likes and dislikes, and manner of doing business of the foreign people to whom he would sell. These same companies answer their foreign correspondence incompletely and apathetically. Cases are known in which queries, involving the expenditure of

large sums, when sent to European producers and to this country simultaneously, elicited detailed answers by air mail from the former, with technical data and catalogs, and a mere acknowledgment by ordinary mail from the American companies concerned.

The answer is obvious. If we are to repand our expand our expand to respect trade—if we really want to!—and thus keep our farms and factories operating at a higher efficiency, we must develop a new understanding of the problem. It becomes necessary that are to be considered to the control of the problem. It becomes necessary that our system and then use a little gray matter to correct them. The stakes are worth te-for all the Americas.—F.D. M.

Degrees, Comfort

E VERYBODY knows that there are days when the thermometer is a liar. On a given day in midsummer, let us say, it stands at 88 degrees, which is really hot in some places, yet the day may be quite agreeable. Perhaps on the next day the mercury has fallen a full ten degrees. yet life may be almost unbearable. We say that the first day was dry, while the second was muggy. In more scientific terminology, the relative humidity-that is, the ratio of the amount of water vapor mixed with a given amount of air to the amount that the same air will hold at the same temperature—has changed from low to high. Moving up more closely to what actually goes on when the muggy day comes, the number of water vapor molecules in the air has increased, the effect is to cause a larger number of speeding molecules to leave the air adracent to the victim and add themselves to the sticky film of liquid in which he is bathed, in proportion to those which, similarly speeding, simultaneously escape from him. Thus his net evaporation is reduced and he probably goes around all day "beefing" about it's being hot and getting himself glared at by others who already know it. Yet on such a day it isn't as hot as it was yesterday when it was so comfortable.

A thermometer gives but one factor in measuring bodily comfort; relative humidity adds a second, while a third is str movement.

An matrument combining these three factors is now available but before its use can become widespread the public must be taught what relative humidity is. By publishing relative humidity percantages some newspapers arouse curriculty and in time the scientific point of view may be inculeated. Good work—keep it up.—4. G. I.

Personalities in Science

ONE generally thinks of an engineer as a technical man talking in mathematical terms and thinking with a slide rule. But O. B. Hanson, vice-president and chief engineer of the National Broadcasting Company, is one of the rare exceptions,

"OB." as Hanson is known to his associates, is essentially an artist with the inquisitive mind of a scientist. Thinking in terms of an artist and working as a scientist is the secret of Hanson's achievements in the field of radio and television.

Born at Huddersfield, England, Hanson was brought to this country at the age of one, when his father moved the family woolen business to Connecticut. Young Hanson showing an early aptitude for music and drawing, his family later sent him back to England for eight years of study at the Royal Masonic Institute in Hertfordshire where. in addition to his regular classes, he had special instruction on the violin.

Hanson says that he never really cared for the violin and wanted to play the piano, but his family insisted. However, he had no intention of making music his life work. He would probably have become an architect, if it hadn't been for the sudden death of his father. That event put an end to his ideas for a higher education and, as a boy of 16, he returned to America and went to work in the Underwood Typewriter Company's factory at Hartford. Connecticut.

Hanson's interests became centered on wireless telegraphy in 1912 when the Titanic rammed an iceberg in the North Atlantic and sank with an appalling loss of life; for it was only through the ship's wireless that a horrified world learned of the tragedy. It was not wireless telegraphy as such, however, that intrigued the eager youngster; it was the unexplored possibilities of its development. He soon began to think in terms of radio telephony and, later, of television. Here was work to tax the artist's imagination and bring into play all the skill of the scientist. Here was his life's job, an

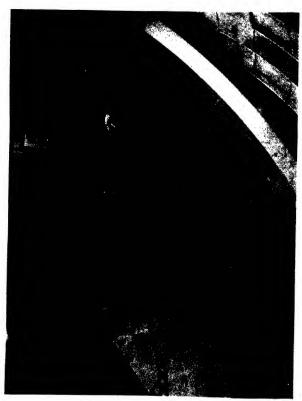

O. B. HANSON

unexplored field in which he could revel In 1917, Hanson became a member of the Marconi Company's engineering staff, rising to the position of chief testing engineer in six months. The war over, he had a short fling as head of his own electrical business in Hartford Then in 1920, station KDKA, Pittsburgh, owned by the Westinghouse Company, had begun regular broadcasting and Hanson built himself a receiver and listened to the first test transmis sions. Immediately his course was de cided. That course led eventually to his present position.

However, as in all good stories, young Hanson started at the bottom of the radio ladder His first job was with station WAAM, Newark, New Jersey, where he held the various positions of chief engineer, operating engineer, program director, and announcer. For all practical purposes, Hanson was station WAAM. In the years that have followed, the world has seen the rapid rise of radio as an art and as an industry. Hanson's own rise has been always a step ahead.

It is not an exaggeration to say that Hanson lives, eats, and sleeps his work. His home at Westport, Connecticut, is a veritable testing ground for technical improvements in both radio and television He designed it himself and it contains many special features that only an artistic man of science could possibly have continued. Even his hobbiesphotography, yachting, and music-become factors in his regular work; photography he finds has given him many useful ideas in the development of television; on his yacht he has been able to carry out much experimental work in marine radio telephone; music is almost a fundamental of radio programs.

Hanson is a bachelor. His present family consists of a registered black and white Springer spaniel with a litter of eight pups. He is a fellow in the Acoustical Society of America, and a life member of the Veteran Wireless Operators Association Incorporated.

WHERE, OH WHERE HAS MY LITTLE TRUCK GONE?

THE huge dome for the new 200-inch telescope on Mr. Palomar, California, is 137 feet in diameter, 137 feet high. Near the top, to lift the giant parts of the telescope, is a 60-ion crane, permanent. During the assembly of the telescope, states Russell W. Porter in transmitting this photograph taken by Ted Watterson, the engineer in charge of construction found a one-ton truck on the ground floor where he had cordered the space kept clear. A fling was attached to the truck and it was hoisted and left 100 feet of the truck and it was hoisted and left 100 feet of the discovered the next morning by the astonisht to be discovered the next morning by the astonisht to be discovered the next morning by the astonisht to be discovered the next morning by the astonisht to be discovered the next morning by the astonisht to be discovered the next morning by the astonisht to be discovered the next morning by the astonisht to be discovered one and telescope.

Diregard of signals causes injury or death to thousands nigury or death to thousands application of the examination methods discussed in the article below, it would be possible to eliminate from the highways those drivers who, because of physical or mental instability, enanto the depended upon to observe those rules of the road which must be hee'ded if safety for everyone is to be arbitreed.

Insanity At The Wheel

SWAGGERING into the Detroit license bureau, T-102 was blissfully unaware of the blow that fate was about to deal him. He had lost his tax driving permit and driver's heense some weeks earlier, and now demanded permisson to resume earning his livelihood by piloting a cab through the streets of the nation's fourth city.

"See Judge Maher," said the man at the counter, and T-102 swaggered out, confident that the judge would restore him to his seat behind the wheel.

Into the austere courtroom of Traffic Judge Thomas F. Maher walked T-102 next morning, and hardly had his law-yer presented a petition for recovery of lost privileges than the judge passed him along: "Have a talk with the traffic psychotechnologist."

T-102 blinked at this command, comprehending not at all, and shortly thereafter stepped briskly from the elevator into the 17th floor hallway of nearby Barlum Tower, opened a door marked "Psychopathic Clinic," and handed across the counter the brief court order requesting his examination.

It was here the 36-year-old taxi driver became T-102, a psychological guinea pig in whom Alan Canty, the psychotechnologist whose official designation had so startled his visitor, took an interest no greater nor less than in any of the many traffic violators who expose their mentalities to his searching inquiry

Canty put T-102 through the ropes, over the jumps, across the hurdles.

To What Extent do Psychopathic Cases Contribute to Motor-Vehicle Accidents?...Weeding Out the Unfit by Specialized Analysis of Attitudes

By ANDREW R. BOONE

Y OU mush into the car ahead, dath past the red signal, send pedatrians serving for asidy as you swing the wheel hard. You must not how contributed You may not how contributed to the c

Physical examination revealed him to be normal. He stood five feet ten inches tall, weighed 190 pounds. His voice was slightly hoarse. Neurologically, he was negative; his vision was found adequate when both eyes were used, though a trifle subnormal when the eyes were tested individually. Depth perception and color vision were good. He was thoroughly familiar with the traffic laws

An inspector from the Police Department's license bureau accompanied T-102 on a driving test. He performed according to the requirements of the law, although . . . mark this! . . making turns violently, blowing his horn excessively, trying to make pedestrians and drivers move out of his way, "thus showing no consideration for the rights of others."

THIS check was by no means conclusive. It demonstrated the man's shill ity to drive, hut beyond that shilliy lay an attitude which Canty explored (curther. He took T102's psychiatric history. He asked many questions designed to hring out that attitude and reveal his level of intelligence. He studied the record Here is what Canty (cond.)

record. Here is what Canty found:
During the 15 years which T-102 had lived in Detroit, he received 287 tickets for various traffic violations. "Minor violations," explained the subject non-chalantly, as though these infractions had no significance since he had injured no one. That was only the beginning.

dany motor-car accidents are caused by thoughtlessness and a disregard of the rights of others. Carried to extremes, such irresponsibility will become "driving lunary"

We'll skip the details, and come to the important point. Canty gave T-102 an intelligence test, found him to pos sess the intelligence of a ninc-year-old child. Further, his intellectual weakness was complicated by his conviction that laws were made to beat, not to obey.

Canty finished the job, passed his conclusions along to Lowell S. Selling, M.D., clinic director, and here's what Dr. Selling wrote Judge Maher

"While this man is certainly not insane in the conventional sense, his conduct is as unpredictable and dangerous as the usual insane person's would be, for he has no more consideration of the rights of others than one who suffers from an actual serious mental disorder. We might call him a 'driving lunatic' because of this irresponsibility. The fact he has had no previous accident record is a matter of luck, and he is bound to get into serious trouble in the future if he drives. In fact, he has continued to drive although he has had no license. Finally, we consider T-102 the most dangerous man to have been examined in the last 200 cases, and, of course, could not indorse the granting of a license to him."

And, of course, Judge Maher refused T-102 a license. Which concludes our interest in T-102 as a case, but not as a symptom.

How many nne-year-old mentalities step on throttles and guide their motor cars through traffic, menacing life and property? To what extent do intoxication, emotional instability, maniae depressive psychosus, pilepsy, faulty mental attrudes in general which may be classed as insanity contribute to the appailing total of deaths and broken bodies?

No one knows the precise cause of

Alan Canty, whose work un psychotechnology largely forms the basis of the present article, is shown, at the lower left of the photograph at right, operating the reactrograph. With this device it is possible to test the reactions of drivers and hence arrive at conclusions regarding mental attitude

all accidents. because few accidents are meetigated thoroughly enough to reach the causes. Then, too, several factors usually are involved. Defects of highway and which, actions of pedestrians and drivers—these contribute. But the drurer, "defective in much or body," according to the National Safety Council, is the most important element.

How may these wholesale killings and myuries by hundreds of thousands be halted—or can they? Traffic safety drives often are accompanied by increased killings. Where, then, lies the remedy? In psychiatric surveys? Do these surveys adequately reveal the "smart alecs," the "show-offs," the lunatics—borderline and real?

"Traffic accidents largely represent a disease," according to Canty, "and we seek the cause."

Detroit is finding the answer—by measuring human aptitudes regarding motor-car operation. Here street conditions are reproduced in the laboratory, and standardized tests evolved by Dr. A. R. Lauer, of Ohio State University, Dr. Morris S. Viteles, at the University of

Pennsylvania, Dr. Harry R. De Silva, of Harvard's Bureau of Street Traffic Research, Charles S. Myers, at the National Institute of Industrial Psychology in London, and Canty bring to light some surprising facts.

One night in late June, for example. a 51-year-old man made a left turn, and, failing to straighten out on the right struck a car approaching along his left. Not much of an accident, but the police, trained to look for unusual behavor, decided to investigate carefully.

"Pretty tight, aren't you, buddy?" one policeman asked.

On the way to the station, the prisoner admitted he could "feel" the effects of a few drinks. At Judge George T. Murphy's request, Canty, put this man, now T-217, through the paces and learned he was suffering from hypertension, had an artificial left hand

and a hernia on the left side of his body.
"Extremely explosive, aggravated by
many years of chronic alcoholism,"
Canty reported. "Suffers inferiority
complex. Very dangerous."

Oddly, T-217 agreed.

"Better put me on probation for six months and take away my license before I kill somebody," he urged.

Canty accepted the recommendation, and Judge Murphy forbade the gentlepan ever again to touch the wheel of a motor car, adding: "We have no sympathy for drunk drivers."

Why revoke a man's license just because his car this another? The accident, as it happened in this case was not the underlying reason. True, the driver had been negligent; furthermore, the happening was symptomatic of perhaps a more tragic collision. Detroiters value their lives. Their judges and psychologists propose to protect them.

T-217 admittedly had had a few drinks, but T-39 was cold sober when he smashed the trunk of a car whose driver had halted for a red light. Now, T-217, remember. was 51 years old, and T-39, it developed, had barely turned

"I pulled up, but my foot must have slipped off the pedal," T-39 told the police, who didn't like his excuse, and booked him for reckless driving.

"The guy must have been talking to his girl friend," the officers reported to the desk sergeant.

T-39 faced Judge Murphy and repeated his story. "Besides," he added, "damage was only seventy bucks."

This time, perhaps. But what about his next accident, and the next? The hoy may have been entertaining his Number One Flame, but, while of average intelligence, Canty's probe revealed these additional significant facts about him.

History of venereal disease, coarse tremors of facial muscles and fingers, considerable motor incoordination, alcoholism, slightly defective vision

atconoism, siignity defective vision Canty did not stop here Perhaps some of these factors were in themselves effects, and not causes. As he proceeded with his examination he uncovered other facts of even greater bearing on that simple crash.

"ITS father," he found, "he a chronic that alcoholic, unstable and irritable. His mother obtained a divorce when he was three, and went to live with a sister who was operating a "blind pig." The boy lived in several boarding homes and was a problem child in several schools. He admits having been arrested three times for being drunk, and recently was held in the Psychopathic Ward of the Receiving Hospital after taking an overdose of barbural.

T-39 had disintegrated, and it was not entirely his own fault. What to do with him?

"Your youth and attitude," Judge Murphy told him later, "make you worthy of help."

T-39 went on probation; his license will not be returned until he demonstrates to the court's entire satisfaction that his mental and physical health make him once more fit for the high-

Traffic authorities, judges, and psychologists have no desire to diminish the number of drivers. They wan thon-catly to protect the public—you and me-by adjusting drivers with correctable defects and eliminating from the streets and highways those too severely maladjusted.

This is the reason for Detroit's Paychopathe Clinic, which is a department of the Recorder's Court. It was established for the sole purpose of examining individuals referred by various courts of the city. To it come those who are convicted of traffic felomes, and those who by their behavior subsequent to arreat lead authorities to think paychiatric examination is indicated. All have been found guilty before Carty gets them. Upon his recommendations rest their punishment and rehabilitation, if any.

If this article seems to harp on attitude, the emphasis is wholly desirable, for attitude of the driver toward the law and his fellow man holds the key to success for this newest cross between judge and detective—the psychotechnologist He never knows at the outset whether he's dealing with a temporarily instable intellect or a dangerously in same driver. Nor is he interested—officially—in what he finds.

T 398 (you will note that Canty identifies none of his subjects, for unofficially he hopes each will somehow

Arrows raised 1/4 of an inch above the surface of the road, some painted white and some black have been installed on this California highway is an endrayor to redure the state's accident rate

escape the damning implications of lunacy) seemed mild enough when picked up for speeding. His tone changed in the courtroom

"These birds," indicating the officers,
"want to get me. They've jimmed up
my speedometer. Honest, your honor,
I'm not guilty."

But in the quet of the laboratory, the 39-year-old speeder unwittingly gave up an entirely different story. Not only had he been in the hands of a psychatrist for treatment, but he was at that very moment suffering from a severe form of insanity. Crazy—and at the wheel!

No jail sentence for T-398. Eloise Hospital got him, where he will be denied all contact with the motoring public until death or medical science separates his physical body from his unfortunate mental deficiencies.

SUCH cases could be multiplied many fold were there such men as Selling and Canty on the job from Sandy Hook to San Diego. from Jacksonville to Jackson's Hole. Every community has these cases, yet so far there is only this fragmentary record of their criminally irresponsible driving.

More than 30,000 likely will perial in motor-whicle accidents in 1939—many of them vectims of men like T-102 and T-398. Make available to Canty the necessary constellation of factors upon which he builds a decision, and he'll soon tell whether John Jones. or you, or me, is a safe bet behind the steering wheel. Green a thousand Cantys, with scores of thousands of "attitudes" explored each year, and we'd have safer driving, need a hundred new hospitals for the insare-per both.

Street conditions, in model form, are reproduced in Detroit's Psychopathic Clinic, and standard tests are used to bring out facts about drivers' fitness

Research On High Pressures

In the past few years "extreme pressure" has gone out of the realm of a scientific curiosity and has become a tool in the solution of practical problems.

In spite of the fact that, until recently man was not able to develop pressures in the laboratory as high as 1,000,000 pounds per square inch, such pressures frequently occur about us in our everyday experiences. Pressures of a few hundred thousand pounds per square inch are occasionally produced in the hypoid gear in the normal operation of an automobile, in roller or hall hearings, under the wheel of a glass cutter. when the bullet of a high-powered rifle strikes a solid object, and in many other cases where two hard objects strike each other. They are, of course, confined to an extremely small space, and have s very short duration. Such extreme pressures in liquids or gases are much less common, but even gas pressures of nearly 1,000,000 pounds per square inch probably occur every day as particles of meteoric matter, traveling with a velocity of 30 miles per second, collide with the very light upper layer of the earth's atmosphere.

Recently an experiment was carried out in the high pressure laboratory of the Research Foundation of Armour Institute of Technology in which a pressure of 1,500,000 pounds per guare inch was developed. This was the highest pressure ever produced experimentally in high pressure investigations. The pressure at the centre of the earth is estimated to be about 3,200,000 atmospheres, or only 32 times as great as the maximum pressure that has been produced in the laboratory.

This increase in range of artificial pressures may clear up many puzzling questions which have formerly been considered impossible of solution. Very the control of the con

A brief survey of the work that has been studied by means of the high pressure equipment now in the high pressure laboratory of the Research Foundation of Armour Institute of Technology will serve to show the great diversified application of such investigations. A Curiosity of Science is Proving to Have Direct Practical Bearing on a Large Number of Industrial Problems . . . Examples of Promising Applications.

By THOMAS C. POULTER, Sc.D.. Ph.D. Scientific Director of the Research Foundation of Agreement Institute of Technology, Obligano

The work was started in an attempt to study a reported effect of pressure upon the chemical reaction of sulfuric acid on zinc to form zinc sulfate and diserted hydrogen. This investigation was carried to a pressure of 30,000 at-mospheres, during which it was found that the effect which we set out to study did not exist. In the course of the investigation we found many interesting things, including a little known chemical reaction of hydrogen on sulfuric acid to give hydrogen sulfide and water.

Other chemical reactions were investigated under extreme pressures, such as the reaction between sugar and water. The rate of this reaction was found to decrease with increase in pressure

From the information gamed as a result of our previous work, new pressure equipment was developed in which it was possible to carry on experiments in cylinders with glass, quartz, or dismond windows, which will withstand pressures of one half million pounds per square inch. In connection with this development many interesting phenomena were observed, such as the ability of glass or quartz windows one quarter inch hick to be bent to a radius of curvature of four inches as many as ten times before being broken.

The development of these windows made it possible to study the effect of pressure upon the manner in which a beam of light, which is vibrating in one plane, is rotated as it passes through compounds which tend to rotate this plane of vibration or polarization. This effect was to increase the rotation of all compounds studied, some of them heing increased to three fold their normal value. Both materials which rotate to the right (dextro-rotatory) and to the left (levo-rotatory) were investigated. This provides a method of studying the progress of such reactions while the materials are under pressure.

The windows also made it possible to study the phosphorescence of zinc sulfide, and it was found that the effect is to decrease the intensity of the phosphorescence by a factor of one half for a pressure of 30,000 atmospheres. It was also found that a rapid change by readded to the second of the control of the one sulfide. Aside from the intensity, the fluorescent and phosphorescent properties of zune sulfide were very little affected by extremely high pressures. It, therefore, provided a convenient method of studying the effect of extreme pressures upon the radioactive decomposition of various materials by actually observing scintillation. These measurements confirmed the negative results of similar investigations by other observers using quite different methods.

Further investigations made possible by the pressure windows were the deter mination of the effect of pressure upon the index of refraction of certain liquida. This investigation showed that the theoretical relation developed by Lorenz-Lorents for the relation between density and index of refraction holds for those substances investigated.

THE quartz windows were further tuitlized in making absorption spectra measurements of the effect of pressure upon the compressibility of the neodynium atoms at the various electron energy levels.

The effect of pressure upon living organisms has been studied, with the observation that 12,000 atmospheres are necessary to kill bacteria, but as the complexity of the living organism increases, the pressure necessary to destroy life decreases. Because of this selective effect of pressure in killing liv-ing organisms and the relation that exists between the pressure required and the size of the organism, it is possible that this may lead to developments of far reaching importance in combating certain diseases. Some small forms of marine life about one fourth inch in length, such as hydra and planaria, were found to withstand pressures of from 10,000 to 20,000 pounds per square inch without any serious damage. The effect of high pressures was to precipitate some of the colloidal constituents of the organism, and a study was made of the precipitation of other colloids, such as suffur, silver, gold, ferric hydroxide, molybdenum blue, and prussian blue. Some colloidal materials are precipitated by the comparatively low pressure of 100 atmospheres, whereas others are only slightly affected by pressures as high as 17,000 atmospheres.

THE electrode potential of the hydrogen electrode was investigated under pressures up to 30,000 atmospheres and the voltage of the Weston Standard Cell up to 12,000 atmospheres. The effect of pressure on both of these is of a lather low order of magnitude.

The effect of pressure upon the pene tration of water and numerous other liquids into glass and metal surfaces has been investigated with some very interesting results. Water was found to penetrate in considerable quantities to a depth of several millimeters into glass in only a few minutes' time The penetration of alcohol and ether is somewhat less, and such houids as paraffin oils, glycerin, and so on, penetrate scarcely at all A similar effect, but to a considerably lesser degree, was observed for the penetration of liquids into metals. The penetration of gases into metals, of course, is more rapid than that of liquid and represents a problem of considerable industrial importance, particularly in the case of penetration of hydrogen into steel whereby the tensile strength of the steel is reduced to less than half its original

The normal dissociation of steam into hydrogen and oxygen, and the subse-quent removal of the oxygen by its reaction with the metal of high-pressure steam lines, particularly under conditions where a high superheat is used. presents a problem of the utmost importance in the high-pressure, high superheat, steam installations that are being used at the present time. It has been shown that considerable quantities of hydrogen are continually escaping through the walls of the high-pressure, high superheat, steam lines, and this subject should be thoroughly investigated to determine to what extent this is affecting the tensile strength of the nietal of the steam lines. If this effect is cumulative, as is the case under the conditions of many of our experiments, it might very well become a problem of great importance in high superheat steam insulation, if not indeed a limiting factor in the industry. We have found that this effect is not only a function of the temperature and pressure, but is also affected by the composition and heat treatment of the steel. It is, therefore, a combination high pressure and metallurgical investigation.

Other fields which have been investi-

A pressure of 580,000 pounds per square inch has been developed in this cylinder (between the four large tension bolts) which contains a glass window in either end for internal observation

gated are compressibility of liquids and solids, the effect of pressure upon the viscosity of liquids, and in some cases the change of state, or even transitions from one crystalline form to another.

A brief summary of the effect of pressure upon the properties of matter will reveal some very interesting facts. The following characteristics for liquids and solids are all affected by pressure: density, volume, index of refraction, electrical conductivity, thermal conductivity, magnetic permeability, delectric constant, optical rotation, chemical reactivity, solubility, phosphoreacence, fluorescence, physical strength, specific heat, latent heat, permeability to gases and liquids, and viscosity.

If we consider all but the last two items on this list, we will see that the effect is anywhere from a small percent up to certainly less than a factor of ten.

But now let us consider the last two items. The permeability to gases and liquids may be of the order of magnitude of many thousandfold, and the coefficient of viscosity of many lubricating oils is increased by as much as

200,000,000 times their value at atmospheric pressure. Some liquids are affected comparatively little by pressures of 400,000 pounds per square inch, whereas some oils acquire a hardness between that of metallic lead and metallic copper. It is, therefore, probable that the lubricant of the future, where extreme pressures are involved, will be a liquid little affected by pressure. This will serve as a carrier for a different material which becomes sufficiently hard under pressure to serve as the lubricant. It is therefore our belief that the permeability to gases and liquids and the effect of pressure on viscosity are the two characteristics that will represent the most fruitful problems for investigation, and certainly are the two that are most likely to produce noticeable effects in industrial processes involving high pressures. Investigation of the permeability of gases and liquids has already been discussed and the viscosity investigation of lubricating oils under pressure probably represents one of the most promising investigations to be carried out in this

Noise Control

If you attend the New York World's Fair and enjoy your visit to the Perisphere, that huge spherical structure which houses "The City of Tomorrow" exhibit, you can credit your pleasure to the new science of noise control.

This Perisphere shows what a scientific attack on noise can accomplish. Without acoustical treatment, this 180-foot diameter room would be a reverberating chamber of horrors. As it is, voices, a symphony orchestra, and moving machinery are boused peaceably and you hear pleasant sounds rather than a silly symphony of noise.

Noise control is a necessity, not a fad The clatter of machines, the din of office equipment, produces deafness and nervous disorders, while the high noise level of modern civilization in all its phases lowers human efficiency and happiness. We know this to be true because controlled tests reveal that employees make fewer mistakes and produce more when their work environment is made quieter, and because the public responds quickly to noiseless products. Thanks to noise control, we enjoy automobiles which really live up to that old slogan, "No Noise But the Wind"; we go to the talkies because we can hear the actors free from the sound of film production and background disturbance; we can fly across the continent without cotton in our ears.

Industry benefits directly from the in crease in sales which follows quickly upon the silencing of a product, but that is by no means the only advantage derived from attacking noise. MachinNecessity, Not a Fad...Controlled at Source...Stopped or Damped by Scientific Design...

Improved Efficiency, Calm Nerves, Less Deafness

By PHILIP H. SMITH

ery which has been re-designed to reduce noise is often more efficient and frequently cheaper to produce than its raucous predecessor. Furthermore, the study of sound has led to the development of machines which employ sound for production control and product inspection, thereby lowering cost

The new science has evolved from many years of study into the nature of sound and its transmission. Work with the telephone, and later with radio, has been contributory because investigators treated sound as a phenomenon to be controlled in the interest of creating wanted sound and subduing

or eliminating the unwanted Out of all this has grown a fairly definite procedure for tackling all noise problems.

Designed to be as silent as possible, the fast-running, "almost human" office machine at the right is further silenced by being mounted on rubber footings. Likewise, the clatter of the wire machine below is dampened by footings which absort vibration and therefore some of the noise. Insert shows the mounting of rubber and steel

Every control problem has two phases. The first phase involves the measurement of sound. Two types of microphones are used for this: one is sensitive to velocity or particle motion, while the more commonly used is sensitive to pressure. The electrical curvuit establishes the electrical curvuit of sound which can be analyzed in terms of frequency and intensity

This first phase is known as the diagnosis. It is essential to the second phase which is the treatment. Most noise is made up of several sounds and the diagnosis seeks to sort out and identify the

varous components. Customarily, the specialist attempts to pull down the highest component and then proceeds down the scale until a level is reached which is considered satisfactory. His achievement is recorded as a lowering of decibels; that is to say, in a reduction of watts per square centimeter of acoustic power.

The engineer's skill centers largely in his ability to bridge the gap between analysis and application; in relating noises to their origin. Once he knows what offends and to what degree, he finds it relatively easy to choose between modes of treatment. Instrumentation alone will not do the job. Ears and past experience must be employed to interpret because noise control has not yet been reduced to a book science.

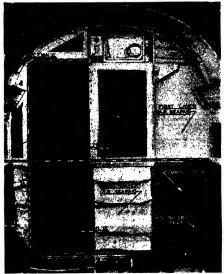

The engineer regards noise as a fact rather than as an abstraction. The elimination is warranted only when there is an irritation to the human system. He seeks, therefore, to uncover the components and reduce them to a non-rritating level. His interest is in making life more bearable, rather than in banishing noise per se.

The fact that noise is always relative and that this relation is an integral part of the control problem is well illustrated by reference to the automobile. The seasoned car owner may recall the experience of coasting with a dead engine. to become conscious suddenly of many annoying chassis and body rattles hitherto unnoticed. With the engine sputtering again, the rattles became lost in the general clatter Engineers met a similar experience when they undertook to silence automobile engines to make them what we now enjoy. When the engine was made less objectionable other noises became prominent and so treatment was carried from one unit to another to achieve an overall benefit Similarly, air-conditioning equipment suitable for city buildings has been known to be unbearable when installed in suburban dwellings where the background noises were lower

WHILE the passenger automobile illustrates the general problem of noise control it is by no means representative of details. Every noise problem tends to be unique, and to demand its own particular method of solution once it has been analyzed. The silen cing of auditoriums, for example, involves the exclusion of street noises as well as the treatment of sounds gen crated within the structure. If the entertainment sounds are to be pleasurable, the specialist proceeds to determine the timing, direction, and strength of noises and to select the proper material to subdue the unwanted sounds without impairing the quality of the voice or instrumental performance. In early days of noise control when the science was less exact, sound-proofing was often overdone, with the result that the entertainment sounds were rendered

Thick pads of glass wool next to the skin in the curved fuselage celling of a Clipper plane

Sound-proofing installation in the forward cabin wall of an airliner. Several kinds of fibrous sheets are built in. They include a coarse paper and felt

hteless, especially in radio studios. The afore-mentioned Perisphere is really a unique auditorium calling for special treatment. It has the curred callings and walls surfaced with a sound-abordent bard made of shredded wood fibers and backed by two other absorbent materials placed m alternate squares. Some eight feet behind this surface treatment, a mineral wood prod-

uct placed between the structural steel girders and lining the inner surface of the sphere's outer shell, traps whatever noises get past the inner wall and prevents reverberations from annoying the audience.

Often an important factor in the silencing of public buildings is attack upon air conditioning and operating machinery. Sometimes it is necessary to dampen blower noises, and to line air ducts and re-design outlet grilles to reduce the sound of rushing air. More and more the practice is read more the practice is re-

sorted to of suspending heavy operating machinery on rubber-in-shear to prevent the transmission of sound vibrations.

It is possible to contrast the problem of noise control in the treatment of structures by citing instances of silen cing a telephone booth and an aircraft engme test building. By studying the course of sound travel a very interesting booth has been developed which has no door and, therefore, does not get stuffy or become a steam bath on hot days. Sound which enters the open side is trapped by absorbent wall surface materials, while the exterior is treated to reflect and disburse the bombardment of unwanted noise. In the case of the aircraft test room, silencing the engine itself was out of the question as the purpose of the test was to take measurements running under normal operating conditions. Here, the building housing the engine was made as sound-proof as possible while the exhaust was carried by vertical stacks to a great height to be expelled with little annoyance to the investigators as well as the surrounding neighborhood.

Where there is motion there is apt to

be noise and thus transportation equipment of various types has been receiving a great deal of attention Recently. a silenced train was placed in operation on one of New York City's subways to demonstrate very convincingly what can be done in the way of insulating, absorbing, and otherwise dampening out noise to make travel more comfortable. Even track has been tackled from the noise elimination standpoint. In this same city, rubber tie plates have been tried out under normal operating conditions to determine the cushioning effect of placing the rails on rubber While a measure of comfort is provided for passengers by this new device, the principal advantage accrues to adjacent building structures and to rails and rolling stock. About 90 percent of vibrations is prevented from reaching the buildings, while the life of rails and rolling stock is substantially lengthened. It is a little early to forecast an overnight adoption of rubber tie plates, but there is a strong likelihood that they will come into use where the greatest damage is inflicted by impact, such as on curves and on bridges.

RUBBER suspension plays a very mortant rôle in the silencing of modern trolleys, buses, and streamlined trans. but much progress remains to emade. Noise control got its foothold in the luxury end of transportation and has still to make its real contribution to mass transportation vehicles via the road of silent design.

Apropos of rubber suspensions, a case can be cited which illustrates how easily the amateur noise controller can be led astray in his quest for silence. It is common practice to suspend heavy machinery at four points, although threeInstallation in a school of a Celotex product which effectively absorbs manufactions and echos. At right: John-Manville sound deadening material being packed into the cushioned floor chairs which are part of a special "floating" construction that efficiently controls all noises

point suspension is often more satisfactory because it insures an even distribution of weight at all times Knowing the efficacy of jubber suspension, one practitioner concluded that the more rubber the greates the absorption and placed a channel or frame of rub-

ber under a machine im place of four blocks. It failed to silence because of the sealed-in area under the machine which permitted no escape of air as the machine rose and fell minutely in operation. In short, the vibrations were transmitted to the foor acting as a dasphragm under the action of compressing and decompressing.

occompressing.

Noise control engineers have practiced long enough to avoid such mistace: they know what can and cannot be done. In early experiments with the bedough the control of the

If it is permissible to call a tank and

a submarine transportation vehicles, they can be mentioned here as examples of highly important noise control work, even though the details are lacking. The interior of a tank is a poor place for survival at best and its operation has been hampered by the terrific din which military authorities now seek to subduct. At least one European Power is hard at work eliminating the noise from submarine operation to render the vessel more immune to discovery by sound detectors in the hands of the enemy

It is now a well substantiated fact that silence can be had at less expense if built into a product, rather than by removing noise after manufacture. Offien it coats less to produce a quiet machine than to manufacture a noise on one and there are innumerable examples of noise control work which has led straight to lower production cost, more efficient operation, and larger sales of the product. One noisy element in an otherwise well silenced product may be a large obstacle toward its wide use.

Consider for the moment the case of a street car which emitted a noise like a siren. When snalyzed, it was discovered that the frequency of the sound was dentical with the number of revolutions of the ventilating fan multiplied by the number of blades. With this clue the nebre was tracked down and eliminated by allowing sufficient room for the rushing air to pass between blades and the metal outside ribs of the fan.

Outstanding among the examples of built-in silence is the modern commercial transport plane. One will recall the ploneer days of commercial Sying when only the application of cotton to one's ears made transportation bearble. Today, cotton is a surplus commodity in aviation because the plane producers called in noise engineers to check design features in their relation to noise creation and transmission. The silenced plane did not arrive overnight. The first, effort, that of trying to find a

sound-proof material to wrap around the plane, proved fruitless. Materials satsafy different acoustical needs and these had to be differentiated and evaluated as to their insulating value. More important, the sources of din had to be located and classified in the order of their importance, then tackled separately and jointly, because it was an other discovery that silencing one component accomplished little: all contribu tory sources had to be treated.

By far the worst noise offender in an airplane is the propeller, and not the engine as might be expected. Engine exhaust ranks second and engine clatter third. Improvement came by increasing the distance from the tip of the airscrew to the fuselage and designing so that baggage or utility rooms would lie in line with the propeller; likewise exhaust was led to discharge as far from the cabin as possible. Engines are, of course, sources of vibration and, to overcome some of the disagreeable effects. flexible mountings were developed. Then, to improve conditions within the plane, the floors were suspended so that they virtually floated and windows were given flexible mountings in rubber.

most every instance where the result is outstanding.

Thus far we have made no comment upon sound deadening materials. This is wholly intentional; science and technique precedes materials and their application. Acoustical materials number in the thousands. They embrace a host of fibrous substances in countless forms, felts and felt compositions, cork, plasters, different forms of rubber, various combinations of hard and porous materials, almost without end. Each has its own peculiar combination of properties and the choice for any application requires experience and judgment.

Noise control is in its infancy despite the rapid advance made within recent years. One has only to jot down a partial list of all the products which have not been silenced to reach his own estimate of the future. At the same time it would be a gross oversight not to include the utilization of sound for production control and inspection of products This is a phase and a mighty important one of the noise-control science. It promises rapid development because the few things already accomplished demonstrate a dollars-and-cents saving more

immediate and obvious than that derived from silencing noisy products.

Just as the electric eve has been focused upon productive purposes, so the electric ear has been turned toward industry. The ear is now being employed to regulate the flow of raw material to a ball mill. This device increases ball mill efficiency by 10 percent, while a similar percentage reduction has been made in power consumption. If gains are borne out consistently, the electric ear will undoubtedly come into use for the grinding of such materials as clay, limestone, ailies and cement.

AMONG the instruments developed for product inspection which base on sound for their operating principle, there is one which checks over cans of condensed milk to locate those in which a bit of solder has broken loose to create spoilage. There is another which tests for the quality of abrasive wheels. A good wheel gives off a definite note which rings for a certain length of time when it is struck, and it is quite simple to check the pitch and duration of this sound. A third device tests for gear tooth contour by the sound of gears in mesh. This last device is extremely important as providing still another means for checking gears so that the modern automobile can be operated without an annoving hum at various speeds.

This harnessing of sound opens up an entirely new field and we may expect development here to run parallel with those which endeavor to climinate or lower sound to non-irritating levels. Before noise control could be undertaken in a serious way as a specialized enterprise it had to produce tangible results at a reasonable cost. Those results have been accomplished and the time has come when the specialist comes close to saying: "I can kill so many decibels for so many dollars." This gives the go-ahead sign to industry

graphs sourcesy Boeing Aircraft Co , Celot Douglas Aircraft Co , Inc , B P Goodrie Johns Manyille Coro

an air-conditioned building were it not for the sound-absorbent lining of the ducts. in this case Airacoustic abeets

The foregoing gives but a brief list of noise control elements in modern transport design. It does serve, however, to emphasize the principle of "before" rather than "after" treatment in design, because the accomplishment has been such a large factor in abetting the progress of commercial aviation. The advantages are evident for all to appreciate who fly. There are on the market other products less striking that have been favorably influenced by the patient and thorough work of noise control engineers, notably vacuum cleaners, mechanical refrigerators, and garbage dump trucks, while a good beginning has been made with business machines of many types. It will be found that quiet has been built-in rather than achieved through noise reduction in al-

Our Galaxy Re-Measured

THE most powerful method we have for sounding the depths of space depends upon variable stars of the Copheid type. The remarkable relation between the periods and the real brightness of these stars, first detected by Miss Leavitt at Harvard, some 30 years ago, has been fully confirmed by later studies.

Measured by photographic effectthat is, in violet light—a star of this sort, with period 2½ days, is 350 times as bright as the Sun. For a period of five days the brightness is 550, for ten days it is 830, 20 days, 1500, and, for a 50-day period, 2500 times the Sun's. If then we can find the period of variation which is not so hard if we have enough photographs to work on—we know how bright the star really is; and, knowing how bright it looks, we can calculate the distance.

Useful as this relation is, we are still in ignorance of its physical cause. We have very good reason to believe that variable stars of this type are pulsating -alternately expanding and contracting -and the theory of these changes has been worked out in considerable detail But this theory depends on the laws of gravitation and of gas-pressure. It tells us that a star pulsating with a given period must be of a certain density (lower for longer periods), but places no restriction on its size. The observed fact that stars of a given period (and density) have all the same brightness. and hence the same size and the same mass, must depend in some way upon the manner in which heat is generated from atomic sources inside the stars

WE are pretty sure now that the heat is liberated evenly at the time when the star is smallest, and hottest inside, but we do not know the details. Unless the internal structure of these stars is very queer, they cainon be hot enough made to be a surfaced to the stime of the same than the same of the same

Fortunately, we do not have to wait to understand the process in order to use the facts. Were it not for one obstacle, we could map out all the nearer portion of space, up to 1,000,000 light-years or more. But there is something really in our way—great clouds of thin haze in space which weaken the light

Galactic Rotation Effects, Interstellar Absorption and Certain Dynamical Constants of the Galaxy Have Been Determined from Cepheid Variable Stars

By HENRY NORRIS RUSSELL, Ph.D.

Chairman of the Department of Astronomy and Director of the Observatory at Princeton University Research Associate of the Mount Wilson Observatory of the Carnegie Institution of Washington

of the stars behind them, and make them look fainter than they would otherwise appear. Many of these clouds are sharply defined, and show conspicuously against the background of the Milky Way—but there is an increasing weight of evidence that these are nonly dense portions of a vast thin fog which extends along the plane of the Milky Way to

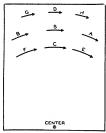

Figure 1 Effect of stellar motions

enormous distances but only a little way on each side of it

When we look at an object, such as a spreal nebula, which lies far out of the galactic plane, our line of sight soon escapes from this dust-haze and enters intergalactic space, which appears to be almost perfectly clear. But distant objects in the galactic plane are much dimmished in brightness, even though there are no obvious obscuring clouds in front of them.

Simple and convuncing proof of the existence of this absorption has recently come out of the admirable work which Dr. Joy of Mount Wilson has done in measuring the radial velocities of Cepheid variables. Since these objects can be seen at great distances, they should be particularly suited for our use in

a study of the rotation of the Galaxy.

Our more persistent readers may recall a discussion of this some months ago [December, 1937 .- Ed.] of which the main point may be repeated here. Suppose that the Milky Way is in rotation about a great mass of stars at its "Center" (Figure 1), and that the Sun S is moving in a circular orbit, at a speed represented by the arrow. Stars at A and B, ahead of it or behind it in its orbit, will be going at the same speed, and neither receding from us or approaching. A star at C, nearer the center, will be moving faster-like a planet nearer the Sun. Its motion will be crosswise, and its distance will not change: but one at E will be running away from the Sun, and receding, and one at F overtaking it, and approaching. Stars on the opposite side will be moving slower than the Sun. There will be no change of distance at D. but the Sun will run away from G, and catch up with H The net result is that stars in two opposite parts of the galactic circle will be receding and those in the intervening quadrants approaching. The greater the distance of a star from the Sun, in a given direction, the greater will be the speed of approach or recession; indeed, this will be proportional to the distance. until the latter becomes a considerable fraction of the distance to the center (when things get more complicated).

THE Sun as not moving in a precisely a circular orbit; but this is easily allowed for. For the stars in the general vicinity of the Sun—say 100 lighty-years—the differences from circular motion will serage out. Hence the motion of the Sun, relative to the general average of these stars, will represent its difference from motion in a circular orbit about the galactic center. It is fairly easy to find this motion, and to allow for

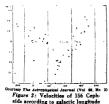

Let us now return to the Cepheid variables. Their observed velocities must be corrected for the "solar metion" just described, and also for the motion of the surface of each star, arising from its alternate expansion and contraction. To eliminate this it is necessary to make many observations of each star, distributed at different phases of the variation, so that a curve may be drawn to represent the changes in velocity—from which a true average value may be derived.

This has made Dr. Joy's work very laborious, as, on the average, a dozen or so plates were needed for each of the 156 stars on his list

When it is added that more than half these stars were fainter than the tenth magnitude, and some of them below the 14th, we may begin to realize what an enormous amount of diligent observing has gone into his results.

When the normal velocities for each star are cleared of the effects of motion of the Sun relative to its neighbors, and plotted against the galactic longitude, a very marked double oscillation is seen (Figure 2). The plot looks rather stars at very different distances, with different rotation-effects, have been combined.

If the stars are norted out according to their distances—calculated on the assumption that there is no absorption of light—it is found (Figure 3) that the nearest stars show only a small effect, and greatly exceeding the deviations for mixedual stars (which represent the differences of their motions from circular orbits). For the next group, the amplitude is great, and for the two templer groups, the rotation-effect great-

ly exceeds the individual motions of the

No more convincing proof of the galactic rotation could be desired; but there are still complications. The average distances for the four groups, calculated without absorption, come out 1700, 5000, 10400 and 20,000 light-years; the half-ranges of the effect are 10, 23, 29 and 38 kilometers per second—and by no means proportional to the distances, as the theory demands. The simplest explanation for this is that there is a general hazy absorption

of light such as has been described above. This makes the more distant stars look fainter and leads to an overestimate of their distances. By "cutand-try" methods-assuming various values for this absorption, calculating corrected distances, and seeing whether the results run in proportion to the observed rotation effects-Dr. Joy finds that a good agreement can be reached with an absorption of 0.85 magnitude per thousand parsecs, or 0m.26 in 1000 light-years. The average distances for the four groups then come out 1400. 3500. 5400 and 7500 light-years. For the nearer stars the effect is not great, hut for the last group it is very serious There can be little doubt that this result is substantially sound, for investigations based on quite different data indicate ahout the same amount of absorption.

Accepting this value, it appears that the depth to which we can study the structure of the Galaxy with the aid of Cepheid variables is limited. Even a very bright Cepheid, of period 50 days, would appear of the 16th magnitude at a distance of 20,000 light-years, and of the 19th at 30,000.

OUR only hope of finding more disobscuration appears to be not uniform, but patchy There are dense clouds in places, thinner ones elsewhere, and nearly clear regions. The value given above is a sort of general average heavily obscured regions we should not be able to see as far; and Joy notes that there are no Cepheids in his list at calculated distances greater than 4000 light-years within 20 degrees on each side of the galactic center in Sagittarius, where the obscuration is known to be heavy Even here, though, there is a chance that there may be gaps between the great clouds, which provide "windows" through which we may see some much more distant objects. A careful detailed study, region by region, is required to detect these, and promising results have been obtained at Harvard.

It is only when we look right along the galactic plane, flatwise through the absorbing haze-layer, that we get into so much trouble. Joy concludes that this layer is 300 light-years thick. Light coming in at any considerable angle to tie plane will not have a long enough path in it to be greatly weakened. This assumption of a uniform layer with sharp boundaries is again greatly oversimplified. It is almost certainly irregular in thickness and thins out gradually.

One thing which the Cepheid velocities give accurately is the direction of the center of the Galaxy—of the line S-Center in Figure 1. This is found to lie in galactic longitude 325° 3 ± 1.3—in very good agreement with other determinations. The distance of the

center is much harder to determine accurately, but the figure shows how it can be done. The point B at which a star would neither approach So rrecede from it lies on the circle BSA, so that the single BS-Center will be less than 90°. If we can determine it, and the distance SB, we can find S-Center. Using the second and third of his groups of stars (which should give the best

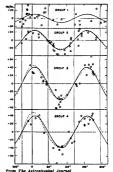

Figure 3. Rotational curves for the four star groups named in the text

values) Joy finds the distance of the center to be 38,000 and 24,000 glaves, The first value should be more accurate, so that he adopts 33,000 lightycars (1,000) parsecs) which again agrees with the results of other observers. This is so much farther away than even the remoter Cepheids that no great difference is made in the calculations, when it is taken into account. (Dashed curves, Figure 3, show results.)

When allowance is made for galactic rotation, the outstanding residual motions of the Cephelds are found to be small—averaging only 11 kilometers per second. As the circular velocity per second, heir orbits must about the galactic center is nearly 3000 kilometers per second, their orbits must be very nearly circular. The pare very nearly in one plane, also, for the average distance from the mean plane is only 200 light-years as against a probable diameter of at least 50,000.

Only one thing prevents these results from being definitive and final. The southern Milky Way, from Carina through the Southern Cross and Centaurus, is below the horizon of Mount Wilson, to that the only spectroscopic observations available in this region are those which have been made with smaller telescopes in the southern hemisphere.—
4.4 Seq. M. V. Britannic, June 30, 1939.

Cuba-Key To Manganese Problem

CUBA today holds what may be the most important single key to America's national security in time of war.

Nine years ago this weam't true Since then, American capital has developed, in Cuba, America's only nearby source of a raw material vital to our national defense—a dirty looking, sooty ore of manganese. This ore is an absolute essential for the manufacture of steel, the metal that wins wars

Attention in United States metallurgoal circles has been focused recently on our national procurement problem as regards manganese and other materials essential to industrial operation, by passage of the \$100,000,000 "stockpile" bill, signed by President Roosevelt early last June. This bill, aimed at reducing the "dangerous and costly dependence" of the United States upon forcing sources of "strategic materials," is designed to encourage development of our domestic sources.

American private enterprise has already contributed largely to solution of one aspect of the procurement problem. The Cuban-American Manganese Corporation, a subsidiary of the Freeport Sulphur Company, has developed in Cuba the world's only plant for concentrating manganese ore on a commercial scale by the flotation processwhich means that they did something that metallurgists had for years con sidered next to impossible. Direct result of this development was that Cuba, which in 1931 provided less than 1 percent of American manganese needs, last year sent us over 25 percent of our total imports for consumption.

The importance of this development may be fully realized only when considered against a background of facts regarding the properties of manganese, and the tenuousness of our foreign sources of supply. Manganese is not just one of a list of more or loss essential materials. Of all the strategic raw materials, it has been rated Number One in importance by the War Department. Furthermore, there are many grades of manganese ore, and not just any grade will do.

Mangauese is the only material which can be used economically as a de-oxidizer and de-sulfurizer in blast-furnace operations at steel mills About 14 pounds are used in making a ton of high-grade steel, and, without manganese, no atteel could be manufactured economically in this country. To be of use to

Manganese Vital in Steel Manufacture...We Have None...War Would Cut Down Imports...Cuba Now Supplies Some...Momentous American Achievement

By RICHARD B. CLARKSON

the steel industry, the manganese ore must be of "ferro grade"; that is, it must have a metallic manganese content

of about 50 percent.
Although deposits have been charted
in 20 states, these are for the most part
of such low grade in their natural state
as to be virtually useless for steel manufacture. Costs of concentration have for
years been considered prohibitive. Concentrating methods other than the flotation process were applied to American
ores during the World War, under the
spur of war-time necessity, but this
work was not conducted on an important
scale after 1918.

Since the war, we have depended for about 95 percent of our supply upon foreign sources, in countries that possess deposits from which high-grade manganese is obtained at exceedingly low labor cost—Russa, India, Afraca, and Brazil. Russis has for years been our number one supplier and, in spite of the Cuban development, still is.

As long as we reman largely dependent upon such remote sources for our supplies of manganese, we face our our supplies of manganese, we face to ment of supply with a flare-up of warm ment of supply with a flare-up of warm almost surely result in the establishment of blockades at the focal points of trade routes serving warring nations of trade routes serving warring nations.

terranean—through which pass shipments of manganese to the United States from both Russia and India.

In the light of these facts, the significance of the Cuban development may be seen as two-fold. In the first place, Cuba is only 90 miles off Key West and there is little possibility that shipments of manganese from this source could be interrupted in the event of war. In the second place, the rise of Cuba as an important source of so vital a raw material is taken by many as pointing the way to possible similar

development of our domestic sources. The Cuban-American Manganese Corporation was formed in 1932, but work preparatory to its formation began as early as 1930, when the Freeport Sulphur Company instigated petrographic studies of ore and rock formations in Cuba. This work was undertaken on samples taken from north of the town of Crasto in Oriente province, on the lower slope of the Sierra Madre Mountains.

DEFORE 1930, many attempts had been made by other concerns to concentrate the Cuban ore, but all experimenters had come to the conclusion that the ore bodies were too irregular in occurrence and too low in grade to concentrate. Fresport's preliminary investigations of the ore bodies revealed that—in their field to the north of Cristo—there existed some high-grade manease ore, varying in manganese content between 38 percent and 50 percent—a grade far too low to 20 percent—a grade far too low be used by steel manufactures.

Previous investigators, however, had confined their experiments to the conventional gravity separation method, which operates on the principle that manganese differs in specific gravity from the material with which it is combined in nature. It was discovered by

Freeport that insufficient difference existed between the mineral and the "gangue" material—ditr—from which it was to be separated, to allow efficient concentration. Other previously-attempted methods of dissolving and precipitating the ore were found to be either inefficient or prohibitively costly.

Having cleared away the deadwood of old methods, the company concentrated verge of profitable operation. It was at this point in 1928, however, that the United States-Brazil trade pact caused such a drop in the domestic price of manganese that operations at the Cuban-harrican plant were immediately suspended. A program of further research was then projected, aimed at reduction of operating costs. The result of this research was installation of the only

rign producers. The practice has been to the allow a preferential of at least 25 percent. With this as a stimulant, and with the Cuban-American development as an encourager, it is possible that the next is encourager, it is possible that the next include the product of the product of the provide for at least the greater part of our domestic manganese industry able to our domestic steel industry's needs for this material.

I N evaluating the Cuban development, and its established and potential ef-

fect on the doniestic economy of the

United States, it should be remembered

that manganese for steel is of course an

essential ingredient of peace-time indus-

trial operation. This is an age of steel

Manganese from Cuban ore pits, like the one at right, promises to solve a large part of the problem long surrounding this material which is essential in the manufacture of steel. By a flotation process developed by Americans—one step of which is shown below these ores are supplying an increasing percentage of our needs for manganese vital in steel production. And without steel, nations would perish, especially in wartime, from lack of guns, trucks, machinery, and other necessary equipment

"wet process sintering kiln" used in the Western hemisphere. Made with the help of F. L. Smidth & Co., Danish builders of metallurgical kilns, this mechanical device "agglomerates" the wet concentrate, accumulating it in casilyhandled lumps or nodules.

Development of the process was, for all practical purposes, an American undertaking, since nearly all equipment of or mine and concentrating plant was purchased from the United States, by American capital. American kas reaped and will continue to reap the benefits in preacting, and may find the development to be the salvation of its steel industry in time of war.

It is probably true that special local terrain difficulties and special difficulties of transportation may preclude the possibility of applying to the ores of the United States the exact process used in Cuba. Nevertheless, it is possible that the Cuban development may serve as an important simulant in implementing the provisions of the recently-passed "notcopile" bill—a major purpose of which is to encourage development of our domestic sources.

This bill authorizes the expendature during the next four years—of \$100,000.000 to acquire stocks of strategar saw materials which are today obtained by the United States largely from shroad. It provides, furthermore, that all purchases shall be made in accordance with the "Buy-American" act of 1933, which states that the purchasing agent may allow a reasonable price preferential to domestic producers, as opposed to for-domestic producers, as opposed to for-domestic producers, as opposed to for-

in which we live. In the past half-century, the capacity of American steel furnaces has expanded over 1000 percent. Today, steel manufacturing is a \$4,200,000,000 industry, third largest in the nation, annually paying nearly a billion dollars in salaries and wages to over 600,000 employes And, just as steel has grown in importance, so manganese imports have increased, soaring from about 250,000 tons of ore in 1930 to over 900,000 tons in 1937 There is a growing universal awareness of the importance of all raw materials in preparedness planning. The effective power of a nation is no longer determined by the extent of its territory, nor by its wealth in gold, nor even

ness of the importance of all raw materials in peparedness planning. The effective power of a nation is no longer determined by the extent of its territory, nor by its wealth in gold, nor even by its strength in armies or equipment in munitions. but rather by its capacity for continuous production of loob-uniled boots and cannot beans, tanks and rifles, ammunition and au-planes. It takes 17 men, manufacturing and distributing war naterials, to keep one man on the fighting front. And for large scale industrialization, raw material is the first essential.

The implications of America's raw materials shortage were cogenily summed up recently by T. M. Girdder, chairman of Republic Steel Corporation, who said: "God grant that this country does not become involved war, yet even if we are at peace while other nations are at war, our supplies of imported metals might be cut off for long periods. Down in Kentucky, buried in deep underground vaults, we have stored away a great pile of gold. The me might come when we would gladly give all of that gold for a pile of deep reartely-needed manganese."

If another M-Das should dawn in America. Cuba will be ready with at least a partial solution to the crisis; the plant production can be stepped up between the condition of the

all subsequent effort on the development of an altogether new system—the flotation method, which "washes" the ore free of impurities.

The method which was finally worked out and is used today at the Cuban-American plant, is a complex one. It involves grinding the ore to "unlock" the manganese oxide from the gangue material; ditution (enormous quantities of water are used in the floatation process); use of reagents for frothing and floating the manganese and for alimediapersing; flooculating; and sintering, which diminates water from the hydrous wide mineral.

Numerous mechanical difficulties were encountered from the beginning, but by February, 1935, the plant was on the

Eyes That See Through Atoms:

(In Two Parts-Part Two)

WHEN the spectroscopist burns a substance in an electric arc to force it to emit light, the molecules of which it is composed are torn asunder. These molecules consist, of course, merely of groups of atoms clinging together in definite patterns. When vitamins or hormones or other such computations or hormones or other such computations or hormones or other such computations.

plex materials are studied, it is the molecules themselves which are of interest, rather than their constituent atoms. Though such materials would be destroyed if burned, fortunately they can be studied with the spectro scope by an entirely different method from the onc used for detecting atomsa method which leaves them entirely undamaged. If a material is at all transparent, light can be sent through it, and waves of certain lengths will be absorbed by its molecules The spectrograph can then be used to obtain information about the molecules by analyzing, not the light which it receives, but that which is missing because absorbed before it enters the spectrograph

Vitamin A, for example, has been found to absorb strongly any light waves which are slightly shorter than violet waves. Therefore, instead of feeding cod-liver oil to rats for weeks to discover how much vitamin A a given sample contains, the standard procedure now is merely to seend a beam of ultra-violet light through the oil, and measure with a spectograph of the procedure now is merely to seend a beam of ultra-violet light through the oil, and measure with a spectograph of the procedure of t

the amount of light of wavelength 3290 angstroms which is absorbed by a layer of oil of measured thickness. Care must be taken to dissolve from the cod-liver oil any non-vitamin material which might absorb light waves of the same length, but such offending impurities can easily be eliminated by mixing chemicals with the oil, which change them to seap.

Analyzing a transparent or translucent substance by studying the light it Spectroscopic Analysis the Supersensitive . . . In Vitamin Research the Spectroscope Short-Circuits the Overworked Rat . . . The X-Ray Spectrograph

Professor of Experimental Physics and Director of the Research
Laboratory of Physics at the Massachusett Institute of Technology

Couriesy Adam Nilser, Lid A portion of a typical spectrogram as used to determine the Vitamin-A content of cod-liver oil. Reference figures at top and hottom indicate wavelengths in angaroms, while the tier of absorption spectra showe difference in light absorption for varying thicknesses of oil, as may be seen by shoosing some prominent line or feature and running it downward.

absorbs is particularly convenient because the material is not destroyed, and the method is quick, clean, simple, and accurate. The two questions which any such analysis must answer are "What substances are present?" and "How much is there of each?" Light absorption measurements answer the second question very definitely. It is estimated that a layer of material only five atoms thick can, in many cases, be detected by the light it absorbs. By combining a microscope with a spectroscope a speck of vanadium only 100 atoms long by 00 atoms brod by five atoms thick has, in microscope with spectroscope is pecked of vanadium only 100 atoms brot bick has

been observed Ability to detect such a clump of matter, containing only 50,000 atoms, weighing a billionth of a billionth as much as a dime, stamps this method as one of the most sensitive available.

ALL life ultimately de-pends on absorption of light, for it is the absorption of sunlight by the green leaves of plants which keeps the plant and animal worlds alive. Biologists have long used the spectroscope in their efforts to learn how the chlorophyll of green leaves manages to capture sunlight, and, with its aid, store in the leaf carbon from the air as cellulose, starch, and sugar. Many a leaf, green or brown or vellow, has been held before the slit of a spectrograph and had its inner structure plumbed with light in an effort to unravel the secrets of chlorophyll and carotin and other complex molecules on which life depends

In the ultra-short-wave region of the spectrum lies a broad band of waves entirely untouched except by the pioneering surveys of spectroscopists studying the

appetrum for its own sake. Such useful applications of these waves as there may be, and there are probably many, must wait until further experiments have been performed designed to perfect ways of handling those delicate rays. No one has yet succeeded in finding a solid material which is transparent to light waves benter than one fourth as long as those we call violet and longer than X rays, and which could be used for windows to allow light to enter and leave experimental apparatus. Thus far hydrogen and helium are the only materials which the ultra-short light waves

^{*}Copyright 1939, by the Author From the boo "Atoms in Action The World of Creative Physics, by George Russell Harrison (Shortly to be publishe by William Morrow and Co)

have been found able to penetrate, and though windows have been made of such tenuous gases, it is something of a trick to do this.

In the realm of the still shorter X rays-waves similar to light, but less than one thousandth as long-almost all matter becomes relatively transparent. Windows of many types are thus available, but the technic of handling X rays is still very crude; we have no lenses to bend them, no mirrors to reflect them, no microscopes to sec with them. In spite of these lacks, two powerful methods of using X rays have been discovered. The first is to take ordinary shadow pictures with them, such as have revolutionized niedicine and surgery during the past 40 years. The second is to send the X rays through a special type of spectrograph

Revealing as is the glimpse through fosh or metal which an X-ray shadow picture gives, it is crade compared with that obtained by means of a spectrograph. Then the glimpse is into the very atoms of matter themselves—even farther into the hearts of these atoms than is possible with an ordinary spectrograph.

N 1912 Dr Max von Laue had the In 1912 Dr. Max von Land brilliant idea that a crystal, such as rocksalt or diamond, might separate X rays into beams of similar wavelength much as an ordinary diffraction grating separates light into its colors. The diffraction grating consists of thou-sands of parallel lines traced on a mirror; the crystal, argued von Laue, consists of millions of parallel lines of stoms, very close together, and perhaps these closely spaced lines are just what is needed to sort out the short-waved X rays. Experiments carried out at von Laue's suggestion showed that his idea was a good one. When a narrow beam of X rays was sent through a crystal, bright and dark spots appeared on a photographic film held behind the crystal, and the positions of these were found to depend on the different wavelengths in the X-ray beam, and on the arrangement of the atoms in the crystal. Sir William Bragg and Professor W. L. Bragg soon were able to arrange the crystal in a spectrograph so that clear, sharp, spectrum lines were obtained with X rays, entirely similar to those produced when visible or ultra-violet light is sent through an ordinary spectrograph.

If X rays are ent through a piece of metal, the small crystals of which it is composed can be studied with the X-ray spectrograph. This use of X rays has particular application in the heat trestment of steel. In one foundry it had slavsy been found necessary to keep certain metal parts for six hours in a furance at high temperature, to bring them to the proper strength and hardness. Then the arrangement of crystals in the

oursey recasology resides

nology. Since air is opaque to light waves shorter than about 2000 angstromall air must be pumped from the light source, the spectrograph, and the camera if such rays are to be photographed. Note vacuum pump and valve air car

metal was studied, and the realmement of the atoms and crystals during heat treatment was followed with an X-ray spectrograph. As a result it became possible to work out theoretically a special short course of treatment lasting only half an hour, and on trial this proved to give better results than the longer treatment, at one fifth the cost.

Peces of metal which undergo great stress, like amplane propellers, usually show changes in their nutrial structure a considerable time before they are acidy to break. Propellers are almost always X rayed by the shadow method, to discover internal flaws, but they should also be studied from time to time with the X-ray spectrascope to insure that their atoms show no signs of wanting to let go of each other.

How well a piece of cloth will wear depends on the quality of the fibers of which it is weven, and how strong and flexible these fibers will be depends greatly on the character of the molecules of which they are composed. The X-ray spectrograph can be used to look right down through the fiber structure directly into the arrangement of atoms in these molecules, and sometimes shows that improved arrangements of atoms would make better molecules, hence sturder fibers, hence stronger cloth.

In cotton, wool, and asbestos fibers the molecules are found to consist of long strings of atoms lying side by side; here are substances respectively of vegetable, animal, and mineral origin which are similar in molecular and in outer form. Mica is composed of molecules which form broad flat crystalline plates arranged in layers which are held together so loosely that they can be split apart without difficulty. In diamond, on the other land, carbon atoms hold

strongly to each other in three dimersions to form crystals which cannot be torn or split, and hence produce the hardest substance known. But change the arrangement of these diamond atoms ever so little and groups of them begin to slip apart, the crystal structure changes, and instead of the lard, abrasive diamond, we have graphite, one of the softest and most slippery solids known.

If a piece of rubber is held between an X-ray tube and an X-ray peetrngraph, the spectrum shows that so long as the rubber remains unstretched the molecules in it are arranged helter-skelter with no semblance of order, but when the rubber is stretched, long chains of molecules appear, which contact and expand like cooled springs. The unusual ability of rubber to atretch and then return to its original shape can be traced directly to the molecules of which it is composed.

About lubrication the X-ray spectregraph gives important information, for it shows that greases and oils contain long molecules which slide over one another in layers.

The physicist has been able to conribute the telephone, the radio, the motion picture, television, and a dozen other adjuncts of civilization, only by using the powerful tools with which he has armed himself for the investigation of nature. Among these tools the spectrograph is outstanding, ever ready to yield new information on the structures of atoms, on the arrangements of the molecules which these atoms form, on the multitudes of substances which can be produced from these molecules, and hence on many of the activities of men, machines, and material university.

Two Elements For One

THE Fifth Washington Conference on Theoretical Physics was sitting in solemn conclave when the news broke. Professor Nils Bohr of Princeton and Professor Enrico Fermi of Columbia rose to open the meeting with an account of some research going on in a Berlin laboratory

Professors Bohr and Fermi are Nobel Prize winners both, and their names are as well known to scientists as Toscaninni's is to music lovers. The Conference therefore expected something extra special. They weren't disappointed.

It was January 26, 1939. A few weeks before, at the Kaiser Wilhelm Institute in Berlin, Dr. Otto Hahn, a distinguished German physicsh, had obtained an uterly unexpected result from some more less routine experiments. Following the original example of Professor Fern. Dr. Hahn and his co-worker, F Strassmann, had for many months been bomberding uranium with neutrons and studying the debris left by this atomic designs and studying the debris left by this atomic studying the debris left by the atomic studying the control of the studying the debris left by the atomic studying the control of the studying th

It would not have surprised them at In fact, they had done so before, or thought they had done so before, or thought they had Radium and uranium are near neighbors in the table of elements, and it is nothing new for scientists to transform one element into another close to it in weight and electric charge.

But it was news, and big news, to discover barium among the debris barium, which is only a little more than half as heavy as uranium II meant that the neutron bullets had succeeded not merely in knocking a few chips off the old block, but in blowing the whole atom assunder with a terrific explosion.

The theoretical and practical import of Hahn's discovery may not be immediately obvious to the laymen. The article will attempt to interpret its significance in later paragraphs. But on the scientists, the new had the same effect as the tidings of gold in California had on the Forty-niners. They flew to their laboratories to find the treasure for themselves.

A few insiders had already jumped the gun ahead of the Conference and of the rest who learned of the discovery through the newspapers. In Copenhagen, Dr O. R. Frisch and Professor Lise Meitner, who had previously wecking with Hahn on the same problem, had vernfied his results ten days earlier. A group of Columbia University physicists. including Fermi, independently thought up and carried out a similar experiment The Most Important Scientific Discovery of the Present Year is also the Biggest Explosion in Atomic History... Splitting the Uranium Atom

By JEAN HARRINGTON

by January 25, the day before the Conference. By the time the meeting wound up its affairs January 28, three more laboratories—at the Carnege Institution of Washington, Johns Hopkins, and the University of California—jomed the horus of confirmation. In a word, Hahn was right. Uranium, and thorum, too throrum is also among the heavest elements), had been split in two by neutron hombardment

THE phenomenon was quickly dubbed rauclear fission," and in the months ensuing since its discovery, nuclear fission has grabbed the spotlight from the "heavy electron" sensation of 1937-8 Dozens of the world's top-flight physicists have been buy as bees, roaming the clover of a new field of research.

The first task of the investigators was to get a picture of what had happened. Dr. Frisch and Miss Meitner promptly supplied a pretty good one.

The nucleus of an element, they point of out, is now thought of as an aggregation of protons and neutrons packed to gether into an inconceivably small space. The number of protons, or units space. The number of protons, or units of positive electric charge, accounts for the chemical behavior of the element. Neutrons are units of weight and have no charge. Together the neutrons and protons make up the mass of the nucleus.

The simplest nucleus is the single proton belonging to the lightest element, hydrogen. Going up the atomic scale, adding one proton and a varying number of neutrons for each successive element, we arrive at last at uranium. This heaviest of elements is invariably characterized by its 92 protons; in its commonest form it contains 146 neutrons as well, giving it a total weight of 236. Two other forms, weighing 253 and 234, also occur in small quantities. These are called the three natural isotopes of uranium, and are distinguished by the shorthand symbols U.W. U.W. and U.W.

Now all the known elements heavier than mercury—that is, thallium, lead, bismuth, polonium, radon, radium, actinium, thorium, protectinium, and uranium—have isotopes that are naturally radioactive. Their nuclei are so complicated that occasionally one will spontaneously simplify itself by shooting off a particle.

We can picture the process nicely if

We can picture the process nicely if we imagine for a moment that the radioactive nucleus is like a drop of water, composed of many molecules. One of the molecules near the surface somehow acquires a little more energy than its fellows and evaporates.

The stage is now set to return to Dr. Frusch and Miss Meitimer, whom we left some paragraphs ago. Their conception of the nuclear fission process continues of the nuclear fission process continues on the analogy of the drop of water. Suppose the H₂O molecules are volently agutated by a source of energy outside the drop. Instead of evaporating graduually, the drop splits in two. Similarly, a ruranium nucleus, stimulated by the impact of a neutron bullet, may divide into two smaller nuclei of routhly creunal size.

These fragments are in themselves unstable. and quickly dismitegrate to form still other nuclei. In fact, a whole series of transmutations generally follows the faston of uranium or thorium. Since Hahn first found barium among the products, he and other investigators have identified antimony, tellurium, nodine, xenon, caesium, and lanthanum in one group; bromine, krypton, rubidium, strontium, and yttrium in another, with many possible additions.

The explanation is simple enough. The original fragments contain too many neutrons in relation to their proton content, and must get rid of them to achieve a stable form. One of two things happens. The nucleus may simply expel a whole neutron, reducing its weight by a unit. Or one of the neutrons may be converted into a proton plus a negative electron inside the nucleus, which promptly ejects the electron. In the latter case, the nucleus remains approximately the same weight but acquires an additional positive charge. thus becoming a chemically different element. Experiments have proved that both these types of disintegration actual-ly do take place.

No one knows yet whether the same two original products are always formed when uranium divides, or what they are But if one of the fragments is barium, with 56 protons, the other must have 92 minus 56, or 36, protons, which would make it an isotope of the gas krypton.

If the barium tries to stabilize itself by emitting an electron, it becomes a lanthanum isotope, which may in turn convert itself into cerium by electron emission. The krypton also disintegrates in the same way, successively be-

coming rubidium, strontium, and perhaps yttrium and zirconium. We can show these chain reactions by a formula where the subscripts represent the number of protons of the products:

$$Ba_{5a} \rightarrow La_{57} \rightarrow Ce_{58}$$

 $Kr_{5a} \rightarrow Rb_{57} \rightarrow Sr_{48} \rightarrow$

Y₃₀ → Zr₄₀
Again, if the two original fragments are strontium and xenon instead of barium and krypton, we may have the following chain reactions:

$$\begin{array}{l} Sr_{ss} \rightarrow Y_{ss} \rightarrow Zr_{40} \\ Xe_{s4} \rightarrow Cs_{s5} \rightarrow Ba_{s6} \rightarrow La_{s7} \\ \rightarrow Ce_{s8} \end{array}$$

In a discovery like this in the realm of pure science. it is always easier to see the theoretical importance than to find a practical application. The fission of uranium has provided a field day for the physicists who like to take atoms apart and find out what makes them tick. It adds a new chapter to their knowledge of the nucleus-the forces that hold it together, the collective behavior of its constituent parts, its reac-tion "under fire," its des-

In addition, it clears up a mystery of long standing, dealing with elements heavier than uranum. When, in 1934. Fermi began his experiments with uranium, he soon found that negative electrons were always emitted under neutron bombardment. We know now that they are usually the products of the chain reactions just described; but at that time nuclear fassion was not even dreamed of. Fermi naturally concluded that the uranium nucleus captured the neutron, converted it into a proton, and excelled an electron.

Here, then, was a supposedly new element with 39 protons, unknown to nature. Moreover, this new element seemed to emit another electron to form another new neucleus of 94 protons. These were called "transuranie" elements, and up until lately they were a headache to the numerous investigators who worked on them. The latter kept finding more and more transuranies; and when they studied their chemical properties they found inexplicable variations. Last No-weake, past a few weeke before Dr. Hahn stumbled on the real secret, he announced that he had found at least 16 different kinds of nuclei resulting from neutron bombardment of uranium. Some of them, indeed, behaved chemically like barium, lanthamum, and other light elements, but they were thought to be isometically the sound of

Three of the reactions that are possible when uranium is bombarded by neutrons. Each borisontal line represents as chemical element containing the indicated number of protons. A represents the formation of transuranium. B shows the split of uranium into bariam and krypton, with the chain reaction that follows it. G represents the division into zenon and strontium followed by its own subsequent chair reaction

topes or isomers of heavier elements such as radium. (Isomers are nuclei having the same total weight but different chemical properties. Isotopes have the same proton content but varying total weights.)

When the announcement of nuclear fission came, it was immediately realized that the electrons were not in general emitted by the uranum nucleus itself but by its lighter fragments. The mystery of "transuranic elements" was practically solved. It does seen, however, that a neutron bluelt occasionally fails to give its target quite enough energy to divide; the uranium isotope disintegrates by electron emission and really does form a new element with 93 protons. But one such problem child is far better than 16.

So much for the theoretical significance of nuclear fission, far-reaching though it is. It is pretty hard to amass as much weight on the practical side of the balance. But our imaginations are immediately seized by the terrific amount of energy liberated when a single uranum nucleus explodes. The two fragments fly apart activated by some 200,000,000 electron volts—a total far greater than that associated with any other atomic phenomenon except cosmic Favs.

The tabloids love to write of blowing

up the world with a gram of matter, and it's not such a sensational idea as one might think. Even a tiny mass has an enormous potential of energy if it could but be freed. It is just such a conversion of mass into energy that speeds the fasion fragments on their way.

The weight of any nucleus is never quite equal to the aum of its individual protons and neutrons. A small proportion of their mass, called the "packing fraction" or "mass defect." is somehow transformed into the force that holds the nucleus together. Otherwise the positively charged protons would all repel each other and scatter in every direction.

The packing fraction for uranium is, because of its large number of particles, greater than that for the simpler elements into which it divides. This difference in energy is released with the two fassion fragments.

OF course, 200,000,000 volts is an astounding energy compared with the size of the bodies which possess it. But for practical

purposes it is absurdly small, amounting only to about three ten thousandths of an erg. In more everyday terms, it would take 25,000 billion fassions per second to produce one horsepower—figures which dwarf even the national budget. The very best a laboratory can do so far is produce a few hundreds per second.

If atom smashing could be made more efficient, power production by means of nuclear fission would not be beyond the realms of possibility. But under present conditions, the process is as inefficient as removing the sand from a beach a grain at a time. Or, more graphically, it is like shooting with buckshot at a netwood of beads strung yards apart. The size of the target is comparable with the size of the projectile, the empty space between targets is enormous compared with the diameter of either, the stream of bullets cannot be well controlled or aimed, and therefore it is much more probable that a neutron projectile will fly past a uranium nucleus than to score a direct hit and be captured. In fact the chances are thousands to one against fission taking place.

Neutrons have proved themselves more efficient atom-busters, however, than other projectiles like protons or alpha particles, which are positively charged and hence repelled by the positive nuclei. To get a stream of neutrons, a preliminary bombardment must take place. One common method employs the radioactive gas radon, which spontaneously emits alpha particles (helium nuclei with double charge and mass four). The alpha particles are allowed to fall on a sheet of beryllium, where they join with the beryllium nuclei to form carbon plus neutrons. The reaction is shown by the formula.

 $Be_4^0 + He_2^4 \rightarrow C_6^{12} \rightarrow C_6^{12} + n_0^1$ where the superscripts are the atomic

weights and the subscripts the charge. The stream of positive particles from the cyclotron may also be used to bombard beryllium and thus produce neutrons. The high energy and great number of cyclotron particles make them more efficient neutron makers than the natural radio-alpha particles

Once created, the neutron beam is directed against a uranum target. The products are studied in various ways, if the investigators want to find the energy of the fragments, the target is placed in an inouzation chamber, falled with a gas at low pressure. The fragments ryp through the gas atoms, disrupting their outer electron structure to form ions. The gas sions are drawn to a wire where they constitute a tiny electric current; and the magnitude of this current gives a clue to the energy of the fission products.

If the experimenters want the range of the particles—that is, the distance they travel before their kinetic energy is all used up—they may choose a Wilson cloud chamber which automatically photographs the track of ions the nucleus leaves behind it.

If they want to know the number of fissions occurring in a given time, they have an electric counter at their command, based on the same principle as the lonization chamber. A modification of the same instrument is used to look for electrons or neutrons emitted in the fission process or in the chain reactions that follow.

The problem of identifying the products as a non-what different one, and is complicated by the large number of celements which may be formed. Here the debris is collected on a sheet of Cellophane or paper placed close to the uranium target. Each variety of isotope on the sheet has a definite rate of disintegration—it may be anywhere from a fraction of a second to several days—and this time is characteristic of the clement to which the isotope belongs.

To measure this period of decay, the collecting paper is placed near an electric counter. If the activity of one product decays to half its original value in 87 minutes, for example, that product is immediately known as an asotope of barium, Ba 122, which is known from other experiments to have a characteristic "half life" of 87 minutes. The difficulty of this method of identification is, of course, in separating the half-lives when two or more elements are decaying.

Steroscopic cloud chamber photograph showing tracks of two heavy fragments receiling in opposite discretions from a uranium nucleus struck by a neutron. The uranium is on a colloidon film (one of the broad, bright horizontal lines). The fragment tracks are fainter and fragment tracks are fainter and lower end of the track resulted from a collision of one fragment with a gas atom in the cloud chamber. The double picture is obtained by photographing the chamber amultaneously from two points of use, to get three-dimensional perspective, and the properties of the collision of the c

together, and also in classifying a halflife belonging to an isotope previously unknown.

Another method of studying the products is to perform the experiment under water, then analyze the water chemically. Suppose we suspect that a few nuclei of radioactive lanthanum are present. This is too small a quantity to separate directly. But if a larger amount of a stable lanthanum compound is added to the water, both stable and unstable lanthanum atoms can be precipitated out. If this precipitate is then shown to be radioactive, we have proved our suspicion was correct. Similarly the water can be tested for radioactive barium by adding a stable barium compound, and so on.

STILL a third attack on the problem of identification has been made by Philip Abelson at the University of Galifornia. He had been studying the natural X rays from the supposed "transurance elements"; and put on the right track by the discovery of nuclear fassion, he quickly showed that these X rays had

wavelengths characteristic of iodine and tellurium.

Research along all these lines is proceeding at breakneck speed. Experiments similar to those with uranium have been performed on thorium (Th 20) with similar results, except that only fast neutrons are effective splitting the thorium nucleus, while both fast and slow work well on uranium. Other heavy elements, such as gold and tungsten, show some slight tendency to undergo fission

Fermi and others have been trying to determine which of the three uranum sotopes are involved, and how the procres is related to the speed of the neutron projectiles. Duke University scientists are investigating gamma radations connected with fission, and the University of California is piling up data in all branches of the research. Bohr at Princeton. Solomo in Paris, and many another are concerning themselves chiefly with theory.

Irème Curse and P. Savitch, who were responsible for much of the ground work enabling Hahn to identify the products of liss fission experiments, have been carrying on the classification work in Paris. Joliot, as well as groups of physicists at Columbia, the Carnege Institution, and Cambridge University, have concentrated on the study of secondary neutrons emitted at the moment of fission and matter reactions of fission and matter reactions.

The latter problem brungs up an in-teresting and rather disturbing aspect of the case. These secondary neutrons constitute a fresh supply of "bullets" produce new hissions. Thus well are faced with a vicious circle, with one explosion esting off auchter, and energy being continuously and cumulatively released. It is probable that a sufficiently large mass of uranium would be explosive if its atoms once got well started dividing. As a matter of fact, the scientiats are pretty nervous over the dangerous forces they are unleashing, and are hurriedly devising means to control them.

It may or may not be significant that, since early spring, no accounts of research on nuclear fission have been heard from Germany—not even from discoverer Hahn. It is not unlikely that the German government, spotting a potentially powerful weapon of war, has imposed military secrecy on all recent German investigations. A large concentration of isotope 255, subjected to neutron bombardment, might conceivably blow up all London or Paris.

It has been impossible, even in this long article, to mention all the thousand sapects of this fascinating phenomenon, or name many of the able contributors to the sum of information amassed since last January. But the fact remains that unclear fission is the most important scientific discovery of the year, and holds who knows what promise for the future.

PRESERVED IN PLASTICS

TWO methods of preserving indefinitely in their natural colors such agricultural specimens as leaves flowers, fruits seeds, ineets, and other abbiological material have been developed; who chemists of the United States Depart ment of Agriculture. The processes, while supplementing each other, have different fields of application—one for dred and the other for fresh material

In the method studied by Dr. Charles, E. Sando, specimens are suspended and embedded in methacrylate, a crystal-clear plastic. In this process, the specimens must be dehydrated to prevent moisture from clouding the glass-like plastic material. They may be an-drired or dehydrated by use of alcohol or ether

Grains or seeds, insects, or anything that does not lose its color or shape with drying, may be preserved by this method. Once the plastic sets, it can be machined and polished so that the specimen may be viewed from any angle without distortion.

Modern plastics are used to do by intent what the resins that turned into amber did by accident millenia ago—to preserve insects and plant products in full color and natural form. At left and right are specimens embedded in clear plastic

In the second method, specimens are not immersed in plasties but are treated to toughen tissues and set the natural color. At right a spray of peach blossom is lifted from water-removing syrup after being refrierated the proper many planted temporarily between sheets of thin cellulous acetter film and hung up (see left) to cure for a number of weeks. Complete drhydration is accomplished in a drying cabine.

The other method, developed by G. R. Fescanden, is a chemical process for treating fresh plant material in such a way as to toughen the tisuues and set the natural color. The natural beauty of flowers, or the exact appearance of entire healthy or diseased leaves, can be preserved by immerision in specially formulated water-removing yrups. Each plant species requires an individual treatment which has to be worked out from seven general types of formulaes. Specimens preserved by this new

The curing completed, the specimen loses lit temporary film covering and is mounted on a gless plate in a water-reddent, reshouse compound, reddent, reddent, reshouse compound, right) is then placed over it for protection. It is finally added to the collection (at left) which is being kept for observation to determine keeping qualities of the specimens. If they keep well, the process will prove very valuable as a means of making records for study, research and exhibition

method are sealed between sheets of cellulose film.

Due to the expected permanence of specimens preserved by either method, excellent records of both healthy and abnormal plants and insects may be made available for research and study,

Although numerous specimens have been prepared by both methods, there are a number of difficulties to be overcome before the final methods can be released for general use.

HIGH BLOOD PRESSURE

WHEN Sir Marc Armand Ruffer made his medical study of ancient mummies found in Nubis he reposted that many of these worthies had suffered from hardening of the arteries. Dr. R. H. Hoffman, commenting on this his "Struggle for Health," sad it was natural to assume that the ancient Nubians had high blood pressure.

Yet, he observed, they did not amoke. Supposedly they did not drink hard liquor, overact meat take too much or too little exercise. They did not hive the hurried, bustling, frensied lite of modern times. Syphilis was presumably then unknown also. Yet many modern doctors believe these things cause high blood pressure and hardening of the

In the Archives of Internal Medicane for July, 1930, you will find on interesting study by Drs. Walter C. Alvares and L. L. Stanley of 6000 princeners and 4.00 prison guards. The guards had higher blood pressure than the prisoners. The prisoners were both more calm and less obese than the guards. Possibly nervous excitement entered the picture here. The guards' blood pressure was taken when they came to apply for the job, presumably somewhat excited. The prisoners, unworried and calm, would lead to have lower blood pressure.

It was found also that the bloodpressure level did not rise with age. It was affected little if any by habits of dissipation, by the use of tobacco, alcohol, or drugs, or by veneral infection. Cool weather alightly raised the blood pressure abent high blood pressure appeared to be a matter of heredity and "nerves." Even the impassive Chinese usually develops higher blood pressure when he comes to buelling America.

BUT what is "high" blood pressure? What might be high for me might, all things considered, be normal for you. In 1928 Dr. Herman O. Mosenthal delared it was quite difficult to distinguals between normal and high blood pressure by making a single test. The patient must rest and be under close observation for some time.

There are several types of high blood pressure (hypertension) too, some mild and almost harmless, others not so harmless. Patients with a benign type of the ill return to normal blood pressure after a little rest.

Dr. Mosenthal, mentioned above, also tells of curing one woman's high blood pressure (at least for the time) by preVarious are the Possible Causes of this Ill, but Worry and Nervous Excitement Probably are Large Factors...Calm Rest the Best Cure...Loaf, Loaf, Loaf

By T. SWANN HARDING

scribing freedom from community committee work. This was after she had unsuccessfully taken two sanitarium rest cures and a prolonged trip South, and

had had a major surgical operation
The relationship that should exist between blood pressure and age, contrary
to much lay opinion, remains unsettled.
Dr. Temple Gray told the British Hunterian Society in 1929 that the expres-

Apprehension when the blood pressure is taken may actually cause the pressure to rise abnormally

sion, "A man is as old as his arterice,"
had done more harm than any other
medical statement. He said some people
attain advanced age with their arteries
in seemingly hopeless condition; others
die young with apparently healthy
arteries. He claimed to have seen persons in apparent health with extremely
high blood pressures. Other doctors say
women can withstand such hypertension
well but never men.

Some physicians speak of a "lowblood-pressure type." It consists of artistic persons who suffer from leasitude and an inability to do intellectual work. They come to doctors much earlier than the high-blood-pressure type.

the high-blood-pressure type.
Others speak of racial high blood pressure and admonish us to adopt a vegetarian diet because the Chinese and the East Indians have low blood pressures. But the Eakimos also have relatively low blood pressure and no undue

affliction with kidney trouble, yet they eat only meat. What part does diet play in producing high blood pressure?

Dr. Mossail and his associates reported upon stensive studies of applicants for insurance in The Journal of the American Medical Association for Aprilla, 1937. They wrote: "People with hypertension on not habitually eat more protein or more salt than normal persons. There is no evidence to show that a low protein diet followed by a hypertensive patient, will materially reduce the blood pressure provided there is no amenia."

WOMEN, it was found, tend to adopt that the distribution of the sure do not follow this trend. Neither the salt not the fluid intake affect the blood pressure. Alware has shown in his studies also that, though women are as a whole more prone to constipation than men, men have higher blood pressure. In general, constipation and low blood pressure go together.

There is, then, no average normal blood pressure for persons of a certain age or weight. Each individual must be considered as an individual. The question is: Is this specific blood pressure high for this particular individual at this time?

In an editorial review for the Journal of Nutrition, in July, 1932, Dr. Fritz Bischoff pretty thoroughly showed that there is no evidence that diet has anything directly to do with kidney and blood vessel changes. Why, then, do high-blood-pressure sufferers go on diets? Thirty-odd years ago, when high blood pressure was discovered, it was thought to be due to the kidney disease called nephritis and to the loss of clasticity in the arterial walls called arteriosclerosis. These ideas continue to hang over, though it is now known that primary kidney disease is rare and arterial hardening usually moderate. The dietary restrictions came in with these old ideas. Time has proved most of them to be silly and unnecessary. Even restrictions against exercise have been removed, provided the exercise be in moderation. Above all, the sufferers must avoid stress and strain, for it has repeatedly been shown that, in some, a little rest lowers blood pressures almost miraculously.

Salt is often denied high-blood-pressure sufferers, perhaps for insufficient reason. The best medical authorities now agree that, within ordinary limitations, the salt intake does not affect blood pressure. Prolonged investigation of 11 patients was published in Archives of Internal Medicine for October, 1929, for example. Sometimes these people got as much as an ounce of salt a day, sometimes only a fifteenth of an ounce or so. This was done after an initial period of rest in bed on a good diet for from ten days to two weeks. Occasionally salt was injected into the veins of the subsects in considerable quantity, but their blood pressures remained unaffected.

Low-protein diets came in with the theory that kidney disease and high blood pressure were related. Today, the very assumption that long-continued excretion of the digestive end-products of excess meat consumed will irreparably injure the kidneys, is questioned More over, even sufferers from degenerative kidney disease must have a minimum of protein or they will start to digest their own tissues. If high blood pressure is uncomplicated by such kidney degeneration the meat tabu seems unwarranted The diet has been proved to have very little to do with directly causing kidney, heart, and blood-vessel ailments.

WHAT about other conditions assotiated in the popular mind with high blood pressure? Constipation often accompanies low blood pressure. Obesity tends to promote high blood pressure and is bad for its sufferers.

The death rate of those who suffer from high blood pressure in acute forms is very high. These deaths occur from three general causes, heart failure occebral degeneration being commonest, some form of kidney failure more rare However, the death rate of those with only moderately high blood pressure is about that of normals.

There is a tendency for nervous people and neurotics to have hypertension. Acute infections and intestinal auto-intoxication—assuming the latter exists, which those who appear to know most now deny—do not seem to increase the blood pressure.

Thus, in The Journal of the American Medical Association, September 20, 1990, we find a doctor claiming to have gotten excellent results on 200 patients by using biamuth subnitrate. But in the same journal for February 13, 1932, Dr. David Ayman reported his complete in-ability to get positive results by pre-scribing this drug for from three to nine months in treating 15 high-blood-presuments in treating 15 high-blood-presuments in treating 15 high-blood-presuments in treating 15 high-blood-presuments.

Traditionally, metropolitan life with the strennous excitement of its stock exchanges and intensive life conduces to high blood pressure but a comparable degree of nervous tension can be and often is developed (for reason) on the farm

sure patients. Indeed, Dr. Ayman began to think that this drug and perhaps all other has the form of the perhaps all other has been been as the surface of the treatment used, the investigator always claimed to produce partial or complete relief from the annoying sympose of high blood pressure. Moderate or marked drop in the pressure was always asid to follow. Yet the symptomatic relief was often out of all proportion to the fall in blood pressure, while the blood pressure often fell without relief of the patient's symptoms.

The various investigators had used a wide variety of rest cures, low-salt dieta low-protein diets, and regimens, as well as treatments with heat, the application of radium to the skull, watermelon extract, and all standard drugs used in hypertension. Complete failure was seldom or never reported. Yet there was no cure for high blood pressure! So Dr. Ayman decided to try on 40 unselected sufferers from high blood pressure a treatment that he was sure could not only not aid them but would lack ali effect He used a few drops of dilute hydrochloric acid in water. This at least tasted like a drug and it was enthusiastically recommended when given. The results were miraculous. There was definite improvement in symptoms in 32 or 33 cases! Dr. Ayman wrote: "The symptoms associated with uncomplicated essential hypertension may frequently be relieved by the suggestion inherent in any seriously and enthusiastically prescribed drug or method of therapy. This is the probable explanation of many successes reported in the

past."

Dr. Ayman also found that two weeks' rest abed worked wonders. He found wide variations in the blood pressure taking place without any effort to treat it at all. Obviously, relaxation was most beneficial, as Dr. Mosenthal said in 1928

and as Dr. Arthur S. Grainger told the American Medical Association in July, 1929.

A year or so ago, Dr. H. C. Gram, of Denmark, tried all the most commonly recommended drugs or regimens for hypertension. He found that rest in bed and freedom from worry did more than all else. If the patient was dieted, then the diet got the credit. If the patient was drugged, the drug got the credit rest should have had. If the patient was simply rested, the results were usually as beneficial. Hence the fall of blood pressure under medical care seemed often half-mythical. The first measurement of the blood pressure also is an alarming event calculated to run it up. Hence the gradual fall after "treatment" is often natural but is credited to the treatment.

THE best treatment probably involves televing the conditions in the environment that aggravate a rise in blood pressure. This means: Seek to displace an excitable and to adopt a calm attude. Deall things in moderation. Limit social obligations. Stop worrying, Remember that spontaneous remiseons often occur, that no diet is proved beneficial, that some sufferers resist every recommended regimen. No drug cures, hence take no patent medicines or drug hence take no patent medicines or drug the care of a competent oblyvician.

It is not wise for every sufferer to try arbitrarily to reduce his blood pressure to an assumed normal. High blood pressure is often a benign, compensatory mechanism. One has to learn to abide it. Each patient can be assisted by his doctor to attain an individual comfort level suited to his needs.

High blood pressure has been called the disease of American life, so cultivate the spirit of leisure, loaf more, dream

Conducted by F. D. Mc HUGH

TO DETERMINE MOISTURE CONTENT OF GASES

MOISTURE is an elusive agent—all-detect, difficult to elumnate or control. When there is moisture in supposedly dry annealing gases, high-carbon steel decarburizes and becomes unsatisfactory for

Dew point, and hence moisture content, of gas being read directly

many uses. Razor blades made from it have poor edges; automobile and airplane gears do not hold up in service

To help eliminate this handrap, General Electric engineers have deused a convenient, portable dew-point potentiometer for determining the moisture content of gases. This is done by measuring the "dew point," or temperature at which moisture will condense from a sample of the gas.

A small stream of the gas is conducted through a compartment of the instrument. The mosture condenses on a thin, metallic mirrow which is connected to a thermocouple and then to an indicating instrument. An operator regulates the flow of a cooling medium, usually earbon dioxide, until algabit and condensation of mosture on condensation of mosture on the condensation of the cond

The instrument is expected to prove of special value in steel mills for measuring the moisture content of annealing gases;

also in chemical plants, gas plants, industrial and research laboratories, and in abop tests generally where the mosture content of gases must be known for testing or control purpose. The device weight 16 pounds and is carried in a case 14½ inches long, 8% inches wide, and 6½ inches long.

RING GEARS CAST CENTRIFUGALLY

E XPERIMENTAL work in casting gear hounced by the Ford Motor Company just over a year ago, has been wholly successful, and centrifugally-usy gears now are in regular production

Greater strength, lighter weight, and faster production are the principal ad vantages of the gears made by the new method, according to R. H. McCarnell, Ford metallurgist. By using sand cores in the die, undercuts can be made which would be impossible in a conventional forging, and this saves weight and metal.

Still more important, however, is the

greater strength of these gears made by centrifugal casting Etched sections show the reason I some forgings, times of metal flow are parallel to lines of greatest stress Because of absence of all flow lines in the centrifugal castings, this condition does not exist. The metal is equally strong in all directions

The amplicity of the centrifugal method is especially notworthy. The dies, which are made of a special low carbon steel, are mounted in units of 18 on a turntable Each die begins to spin as it approaches the two initials of the metal to two initials of the metal to two initials of the metal to boldidy, and then stops turning in time for the operator to remove the hot blank and prepare the die for the next casting

SEALING PLATINUM TO PYREX

A SATISFACTORY scal between plati num and Pyrex glass, for use in the construction of chemical and other scientific apparatus, has been developed by Edward Wichers and C. P. Saylor of the Chemistry Division of the Bureau of Standards

The general problem of joining metals and glasses has been studied by many investigators, but the fact that the thermal expansions of platinum and glass are so different has always caused trouble. Thus, when a platinum wire or rod is coated

Turntable on which gears are centrifugally cast in 18 dies

with hot glass, subsequent cooling will erack the glass or pull it loose from the metal. This difficulty has been surmounted by using a seamless tube of platinum instead of a wire or rod. If the walls of the tube are thin as compared with its length (a ratio of about 1 to 12), the shrinkage forces are not great enough to crack the glass internally or to pull the metal away from it

The mechanical principles governing the platinum-Pyrex seals can also be applied to other metal-glass seals of the tubular type. They are simple to construct, and do not require any unusual apparatus or extra-ordinary skill in glass blowing.

GAS MASK FOR OXYGEN INHALATION

AN invention which promises great ability to save lives and restore health

to suffering patients recently was demon strated by a group of Mayo Clinic physi cians at a meeting of the American Med ical Association It is a new gas mask for ical Association II is a new gas mask for giving oxygen efficiently and economically One of the famous Mayo brothers, the late Dr. C. W. Mayo, and its inventors, Drs. Walter M. Boothby, W. R. Lovelace II, and A H Bulbulian, described its promising medical uses to the assembled doctors

One patient, desperately ill with rheumatic heart disease, began to improve immediately when he was given 100 percent oxygen with the new apparatus, although he had heen expected to die. The treatment was not a cure, but an aid to the patient's fight to recover.

Patients suffering with gas gaugrene and tetanus or lockiaw have been helped to recovery by oxygen given with this new type of mask. The recovery in these cases is did to the fact that both of these ailments are caused by germs of the kind that cannot live in an atmosphere that contains oxygen

The mask is also being used to give oxy gen to patients in shock or collapse following injury or surgical operation, in cases of abdominal distension, for headaches fol

Although are welding has been used to fahricate the steel frames of numerous Atthough are welding man seen used to santener the step instance of nature of the residences, the platial home shown in the illustration above is the most imposing example to date of this type of construction. Built at Wichita Falls, Texas, this 12-room residence contains 96,000 pounds of steel framework, welded throughout by the shielded are process

lowing or injections into the brain for diagnosis of brain tumors, for migraine, and for a number of lung disorders. The mask liss also been installed on an airline for use of pilots and passengers threatened by oxygen-lack at high altitudes

The reason the new apparatus is funding such a wide field of usefulness is becauit can be used in the patient's home as well as in large, well-equipped hospitals and be cause it reduces enormously the cost of oxy-

Patients suffering from many types of diseases are relieved by in-halation of oxygen, or an oxygenhelium mixture as shown above. through a newly developed mask. In the drawing at the left, note that the mask covers only the nose, leav-

gen treatment. The cost of giving oxygen by oxygen tents, the method used hefore invention of the new mask, is from \$12 to \$25 a day. This has prevented the use of oxygen except in very few cases, chiefly severely ill pneumonia patients. With the new apparatus the cost of the oxygen should average only \$5 to \$8 a day, Dr Boothby stated

The reduction in price, made possible by the efficiency of the apparatus, will enable doctors to use helium quite generally in the treatment of asthma. Until relatively recently, Dr. Boothhy pointed out, helium was never used except for the most severe asthma cases, because of the high cost, With the new apparatus, both helium and oxygen can be used, starting with a mixture of oxygen and helium and, as the putient gets better, increasing the proportion of the less expensive oxygen till the patient is getting all oxygen - - Science Service

BLACK ELECTROPLATING

DEEP black deposits, suitable for automobile hardware, business machines, flashlight cases, and the like, may now be applied by electroplating, according to Du Pont chemists The solution used con tains ammouium molyklate, nickel sulfate, and boric acid. It is said that the process offers attractive possibilities, heing superior to black mokel plating and other similar black coating processes.

REMEMBER 'EM'

THERE have been more than 4000 makes of automobiles since the first ear propelled by an internal combustion engine appeared in France in 1868!

HIGHER VITAMIN CONTENT IN WHITE BREAD

LOAF of white bread which has the vitamin-B1 content of a whole-wheat loaf, some five times as much as ordinary hat, some we times as much as ordinary white bread, was predicted to the Massa-chusetts Institute of Technology food con-ference recently by Charles Frey, Alfred Schultz, and Lawrence Atkin, all of the Fleischmann Laboratories.

Vitamin B., or thiamin, is an important factor in nutrition but it is not stored in the body to any significant extent and thus must be contained in basic foods. Cereal products, mainstay of the national diet. are suitable for this but these products. especially bread, have been increasingly deprived of their natural vitaniin content in recent years.

The problem of restoring this loss, some times as great as 93 percent, has been tried along many lines, but the latest

A Douglas DC4 in flight

and most practical employs a new yeast. This yeast contains enough thismin to produce a loaf of white bread with the vitamin content of a whole wheat loaf but without any loss of palatableness Although made by a new process, the yeast offers no new technical problems since its baking prop-erties have not been altered. Possibility of such a loaf at a low cost-increase would be a boon to low-income groups, it is declared .- Science Service.

ACTION OF LATEX ON POLISHED ALUMINUM

VILMS of rubber, applied in the form of latex, are sometimes used as a means of protecting the polished surfaces of metallic mirrors and similar articles from scratches and dust while in storage and during ship ment. When ordinary commercial latex is applied to polished aluminum, however, a bluish discoloration is produced which re

mains when the film of rubber is stripped off Tests made at the National Bureau of Standards indicated that the discoloration was produced, not by the rubber, but by ammonia which is almost universally employed as a preservative for latex When the ammonia is removed, latex no longer discolors aluminum. Ammonia-free later preserved by the addition of the requisite mount of pure formaldehyde is likewise without action on aluminum

A FLEET OF DC-4's

UITE recently the writer had the pleasure of visiting the new Douglas DC-4 at Newark Airport. No matter how blasé one may be, the new airliner gives one a thrill by its size, its superlative finish, and its innumerable modern devices and accessories. It is not at all surprising to learn that W. A. Patterson, President of United Air Lines, has decided to purchase a fleet of six of the new DC-4's, at a cost of \$500,000 each, for use in transcontinental sleeper traffic The decision to purchase six ships was based on a careful estimate of the number of airplanes required to maintain adequate coast-to-coast aleeper service Analysis of the airline itself, backed by the estimates of independent market research groups, showed definitely that there would be sufficient traffic to warrant this bold move This year, for example, transcontinental business is running 32 percent ahead of last year's business.

While we have reported the DC-4 already in these columns, it is interesting to pre-sent the final specifications in brief, with the changes which the airline has saked for and obtained.

The passenger cabin is supercharged to a pressure equivalent to that of 8000 feet above sea-level when the plane is actually flying at 15,000 feet altitude. The produc tion type airplane will have a gross weight of 66,500 pounds. Maximum speed will be 237 miles per hour; cruising speed using 74 percent of rated power, will be 210 miles hour Range at 191 nules per hour, with 42 passengers and 3000 pounds of mail. will be 1425 miles or approximately one half the air distance across the United States The eight fuel tanks will carry 2050 gallons of gasoline Wing span will be 138 feet 3 inches, and overall length will be 97 feet 7 inches.

Cabin accommodations will be liberal The floor-to-ceiling distance will be 7 1/2 feet and the inside width more than 10 feet As a day plane, the DC-4 will have accom modations for 42 people. As a sleeper, there will be berths for 32, with double lower berths on each side of the aisle, and upper singles

Crew will consist of a captain, a first officer and a flight engineer, plus a steward and a stewardess. A K.

AIRLINE TO HELP THE PRIVATE FLIER

T is frequently claimed that the airline operators are inimical to the private flier, and have been responsible for the legislation which limits use of the airways by the private operator But surely there must be some way of preventing hindrance to scheduled operation by irregular private operation, and in general the transport people are most friendly to the itinerants. United Air Lines announces that the company will help the private owner in many ways: by furnishing weather information at all its stations; by providing haugar space at a number of airports, by selling gasoline and oil wherever such service is helpful; by providing mechanic service wherever such service is helpful and permissible. Nothing could be more indicative of friendly co-operation -- A. K.

WHY ALLOYS ARE NOT PERFECT

T is accepted, at least theoretically, that all atoms in a metal would line up in perfectly ordered arrays like millions of dice which had been carefully atacked on top of one another, provided the metal could be frozen at absolute zero 459.72 degrees

slow zero, Fahrenheit-the point at which all gases would solidify and all molecular motion would cease. But there just isn't any place on earth as cold as that. Consequently, whenever two or more kinds of oms are mixed, they arrange themselves in a more or less disordered fashion, bein a more or less disordered rashion, be-cause of motion caused by the heat. The result is an aggregation of jumbled groups of crystals, analogous to millions of dice dumped helter-skelter in a box.

FREEZE METAL PARTS FOR EXPANSION FITS

BY utilizing the extremely low tempera-tures available with a mixture of Solox and dry-ice, a new method for cold-shrink-ing metal parts for "expansion fits" eliminates both the expensive equipment and adverse chemical effects associated with previous brine techniques.

Dry-ice is solid carbon dioxide at a tem-perature of -109 degrees, Fabrenheit, which, in subliming, absorbs approximately 247 B.T.U. per pound Solox is a propri-etary alcohol-type solvent and is favored for this application not only because it remains liquid at the low temperatures but

also because of its non-corrosive properties.

A mixture of dry-ice and Solox will produce a temperature of -97 degrees, Fahren-heit, which is considered suitable for shrinking internal parts larger than 9 or 10 inches in diameter. The part to be shrunk is immersed in the Solox, and pieces of dryice are added to keep the mixture "boiling (giving off carbon dioxide) until the part is sufficiently cooled to produce the maximum shrinkage - Solvent News.

'GIRO DELIVERS

MAIL ON ROOF

T is 25 minutes truck running time from the Camden Airport, New Jersey, to the Philadelphia Post Office at 30th and Market Streets, A Kellett KD-113 Autogiro makes the trip by air in five or six minutes and shuttles back and forth from the Airport to the roof of the Post Office five times daily, carrying a full load of mail each time. Eastern Air Lines, which contracted for this service, receives \$3.86 for each mile fle

Taking off from a post office roof

One of our photographs above John Miller, vetera jiro pilot, and now a captain in the service of Eastern Air, taking of the root after a ran of less than 150 feet. The service has proved a complete success, and other cities such a Chicago, Milwaukee, Atlanta, St. Louis, Detroit, and Los Angeles are subviding the problems and are seeking to establish similar autogino mail ferries. Certainly its application in such work is a remarkable tribute to the utility of the "giro."

of the 'giro.

The Kellett KD-113 is the only government-licensed, wingless, direct-control autogiro. Tilting of the 'giro axis replaces allerons and elevator, and the small rudder

is only used for abrupi maneuvers. The ship is a one-place model with closed cockpli, and a large forward mail compariment. With a gross weight of 2250 pounds, 150 pounds of mail are carried and top specis 103 miles per hour with a 225-horsepower Jacobs engine.—A. K.

AIRCRAFT AS AN

INVESTMENT

RAWSON LLOYD, of Aeronautical Se curity Research Corporation, writing in "Flying Facts," gives ten reasons for buying aircraft stocks Larger air forces sre being organized in all countries; unfilled orders amount to \$250,000,000; huge surcraft orders of \$175,000,000 are to be placed by the Army and Navy during the year; Great Britain and France want to buy another \$100,000,000 worth of our aircraft; more efficient production has in-creased profit margins 37 percent; contractors on Navy orders are now allowed 12 percent profit instead of 10 percent; passenger air traffic has risen 28 percent for first five months of this year; plant expansion has been conservative; labor is not yet unionized; stocks are selling on a low price-tures-earnings ratio. Even though these views come from the supposedly dangerous neighborhood of Wall Street, they must be regarded as reasonable.-A. K.

SEAPLANES CAN USE LAND AIRPORTS

AT least it would appear that sesplanes A can alight on lead, from the exploits of Al Bennett at commercial airplane demonstration given by the Aviston Country Clan of Holesville, Long Island. Mr. Bennett uses a standard Fiper Cab powered with a Chappen noter and fitted with Lead floats. The only departure from 'texnderm' was in the fitting of a steel strip are "was in the fitting of a steel strip."

screwed on the outside of the float keels. Yet Captain Bennett was able to land on the field, taxi, and take-off, without any sign of damage or even wear. Apparently seaplane floats have sufficient resiliency in themselves to take up the shock of landing.—A.K.

SENSITIVE

A CURRENT-detecting device so sensitive that it will measure the electricity earried by one electron traveling down a wire every five minutes, was recently described by Dr. J. S. Allen, of the University of Minnesota. The best previous device measures 20 electrons per second.

Quick-Set resin No. 2, obtainable in black and ivory, is used for producing castings in rubber (latex), lead, and glass ds. After casting, this resin will harden in 24 to 48 hours without the aid of heat or pressure

COLOR DETERMINER

AN apparatus which assures absolutely correct determination of colors at any time of day, irrespective of the surround-ing sources of light, has been constructed by Dr. Tryggve Johansson, of Upsala University, in Sweden.

The machine, which is somewhat larger than an ordinary typewriter, produces an unvarying "mid-day light," by which is unvarying "mid-day light," by which is meant a light corresponding to that obtaining around noon on an overcast day This result is arrived at by using electric lampa equipped with special filters, by means of which a correct composition of light is achieved. The color tester also ex cludes all outer light sources, so that no sort of disturbing light is admitted. The samples to be compared—for example, a couple of pieces of cloth—are illuminated at an angle of 45 degrees from two opposite directions, and the observer is forced by the construction of the apparatus to studthe samples at right angles Through this arrangement, no luster or shadow effects appear on the objects, which is often the e if these are lighted from one side only -Holger Lundbergh.

SHAKES HANDS WITH SHADOW

THE newest addition to the Ceneral Electric "House of Magic" at the New York World's Fair enables W A. Gluesing. director of the show, to say goodbye to his shadow, walk off the stage, and actually leave it behind. And the audience seems to get the biggest surprise when he site down in front of a curtain, gets up while his shadow remains sitting, and then shakes hands with his own slindow

The screen on which the shadow is cast as made of a phosphorescent material. The screen stores up the light which it receives from a powerful spotlight and continues to glow after the light bas been turned off.

And so, when Mr. Gluesing stands or sits in front of the screen, all of it is "charged" with light except the part obscured by his shadow life turns off the house lights, walks away, and all of the screen glows except the part which received no light because of his shadow.

Given a strong enough light, the screen will continue to glow for as long as 10

. . With his own shadow

minutes. The shadow can be wiped out and brought back again by turning on and off the red light of neon lamps. This is off the red light of neon lamps This is the screen, and the phosphorescent light given off by the screen cannot be seen in the intense red light of the neon lamps

MOTORING EYE HEALTH FOR 1940

ADVANCE information that health is heig given important consideration in the design of 1940 model automobiles. along with mechanical perfection, comfort and safety was given recently at a meeting sponsored by Fisher Body division of Gen eral Motors Corporation at the Labliey Owens-Ford plants in Toledo Those at tending the meeting learned that better visibility through laminated safety plate glass is to be stressed by several manufac tmers as a factor for eye health and reduc tion of nervous fatigue

Dr. A. H. Ryan, Chicago research seren tist, demonstrated how polished plate glass transmits true images, whereas objects seen through sheet glass sometimes appear distorted.

"The distortion of images seen through aheet glass in a moving automobile is a major cause of eye-strain and consequent

nervous fatigue," Dr. Ryan said. "In tests we have found that three hours of driving surrounded by sheet glass causes a 62 per-cent greater loss in visual efficiency than looking through polished plate glass. We also have found that people blink oftener when looking through aheet glass and that they can read faster through plate

"These findings indicate that plate glass and the clear view it allows provide greater safety on the highway, which will be recognized as an important factor when it is remembered that approximately 25 percent of all accidenta result from faulty vis

Dr Ryan described automobile driving as healthful exercise for the eyes, "provided it is done under proper conditions."

"Driving gives the eyes an opportunity for long-range gazing-a desirable change from the constant close work of office and factory But the eyes should he allowed to see the world as it really is, not as a carrenture." Dr Rvan declared

WONDER DRUG

THE new chemical remedies of the Prontosil-sulfanilamide-sulfapyridine group are now being used to treat no less than 33 com-mon disease conditions. They seem valueless, however, in the treatment of influenza and colds.

COFFEE PLASTIC

NEW plastic, developed by the H. S. Polin Laboratory of Research in Physics, is unique, particularly from the standpoint of use in South America, in that it is made wholly from the green coffee bean and requires no additional raw materials. Coffee-plastic manufacture will be a highly self-contained industry, because the coffee provides its own chemical plasticizers and catalysis, and its own filler material Its by-products, furthermore, are sufficiently valuable in themselves to defray much of the cost of production.

The new coffee plastic can be produced n a thermo-setting or a thermo-plastic form. It can be produced in green, red, mahogany, lirown, yellow, and ebony hlack merely by the chemical development of its own coloring materials, in which the green coffee bean is unusually rich. (One of its by-

Distortion, caused by looking through safety sheet glass (left), and the clear view through safety plate glass

product fields will be that of vegetable dves and chemical color indicators.) It can be made in varying degrees of hardness and resiliency according to the use for which it is intended. It can be molded, drilled, machined, sawed, and polished, and it can be produced with a wear-resistance superior to wood, cork, or rubber, and comparable with the best grade of linoleum. The thermosetting material can he produced with a compressive resistance of 8000 to 12,000 pounds per square inch, has good dielectric strength at low electrical frequencies, very alight water-absorption, and good resistance to weak acids, fruit juices, alkalis, oils, ketones, and other chemicals, and complete fisme-conductivity resistance. It is odorless and tasteless, and it can be molded at pressures from 2000 to 5000 pounds per square

mAn important by-product of coffee-plasur manufacture is coffee oil Thus oil is rich in chemicals, contains vitamin D, and is suitable for a cooking oil and as a mixing oil for paints. It contains fertilizer and abecterial-growth segrances, and can be used in insecticades, medicines, soaps, and lotons. Other hyroducis are an emulalying agent and a chemical for forming coltons, both valuable to clienuss and chemotics, both valuable to clienuss and chemof course, coffee is already well known. Concerning the cost of manufacture, a

Concerning the cost of manufacture, a bag of coffee containing 132 pounds, which it would cost the government an appreciable amount to destroy, can produce 40 square feet of plastic ½-inch thick, and approximately 1.25 gallons of coffer oil. The manufacturing process involves no unfamiliar machinery or special handling.

RUBBER TIRE INDUSTRIAL CLUTCH

THE same engineering principle that I today is preventing thousands of motorcars from skidding on wet and slippery pavements has made possible a new type

of mechanical clutch that has great promise

of wide industrial application. When the multi-made treat of the Central Dual-10 and Dual-10 metor-car treat specificated, it was proved that, under braking pressure, the many narrow vanes or risks of rubber equirmed into a serpentine form and clung to the road surface with a degree of adhesion never before thought possible. Adhesion being the principal job of a clutch, no matter where it may be used, it-was only a step from the multi-wased tire to the Airfack rubber multi-wased tire to the Airfack rubber.

ground coffee after oil extraction; the extraction product; the reacted coffee plastic compound; and pellets produced by molding the reacted compound

clutch, the multi-vaned surface of which clings to steel with twice the friction coefficient of asbestos or other conventional clutch lining.

The Ardler rubber clutch, which is shown in accompanying illustration, already has replaced multiple disk and other place clutches in various insustations, with complete success. It has the advantage over the conventional clutch in heigh much inspire, as well, having only three of four pass compased with 75 to 100 pieces in the conventional clutch. The Ardler clutch well-disk self-adjusting while other clutches are

alippage is encountered and where loads are to be picked up gradually, the use of friction lining is recommended. When the plain rubber squeegee-tread is used, a reasonable amount of slippage can be toerated if the engagements are not too fre-

The clutches are given special treatment to prevent disintegration by oil fumes. A special rotary seal has been developed to deliver air to the clutch, either by entering the shaft at the end or by a straddle-type

PAINT REMOVER

E XPERIMENTATION with solvents and combinations of chemicals to make a milder paint remover resulted in a recently announced product called Presto. The remover contains no sloohol or caustic so-

lutions but is a combination of seven chemicals and, it is claimed, requires only five or ten minutes to work. The manufacturer also states that Presto seldom requires a second application, will not harm bristles on brushes, raise the grain of wood, or burn through.

Three grades are available; Grade A for fine finishes and delicate woods, AA for general use, and AAA for any finish on metals

PROBOSCIS

LITTLE things do count—heavily at times. Consider, for example, the mosquito's stinger, or proboscis. That pleasant little thing weighs just 0.0000006 of an ounce.

SILVER STEEL

POSSIBILITY of a broad extension of The marine uses of 18-8 stainless steel alloys is suggested by a patent recently granted on protection of the steel against seawater corresion by addition of minute amounts of silver to the alloys, reports The Industrial Bulletin of Arthur D. Little, Inc. The peculiar corrosive properties of seawater have in the past heen a serious, unsolved problem for stainless steel. If a portion of a stainless steel plate is covered hy, say a barnacle, the difference in oxygen concentration near the exposed and unexposed surfaces will set up an electrical potential favoring the formation of chlorides of the metals in the alloy. Since these chlorides are soluble, they wash away, leaving the surface exposed for further attack. Thus a sub-microscopic pit forms and, as it deepens, the difference in oxygen concentration between the pit and the body of the metal increases and accelerates the corresion within the pit. Ultimately the interior is honeycomhed with such pits, although the surface may appear entirely unmarred; and the steel becomes subject to sudden and complete failure, almost

without warning.

A solution to this problem, recently worked out by Professor R. S. Williams and to I seem to I see

quately dispersed, but these are the most popular of the stainless steels.

Many advantages other than corrosion

stance are claimed for the silver alloys. resistance are claimed for the suver amoys. Probably most important, since stainless steel is now considered unsuitable for many nece requiring high heat conductivity, is the reported increase of 26 percent in therconductivity on adding only 0.14 percent silver. Other advantages include provement in the case of machining and ability to take a higher polish. A very uni-form, highly polished surface in itself inhibits corrosion, since it makes inception of electrolytic activity difficult.

MUELCE

MORE than one third the distance around the earth at the equator—8870 miles—is the distance traveled annually by the average American passenger car

TORTUBE MACHINE THROWS 2600-Pound Punches

SCIENCE recently added a new punishment rack to its terture chamber—a 600-pound agony maker aimed at survival of only the strongest steel hlades for use in eam turhines. Built in the Westinghouse Research Lab

oratories at East Ptttshurgh, the novel machine subjects test parts to a concentrated dose of the hrutal pummelling which full-scale parts must withstand inside a turbine.

The weaklings, those parts that are faulty in design, literally fall to pieces, but the sturdy metal martyrs can "take" as many as 10,000,000 heatings, and that's enough to guarantee them life eternal, for all practical purposes, in the production of electric power.

These 10,000,000 blows are delivered in approximately 277 hours at the rate of 600 a minute, according to T. F. Hengstenberg,

research engineer in the mechanics division, who designed the machine.

A motor-driven flywheel throws the punch es at the test piece with a force of 2600 pounds behind every blow. Every time the flywheei turns it pushes a heavy spring to snap a steel lever up against the six-inch metal sample.

These metailic hiows, Mr. Hengstenberg explains, simulate the force of steam rushing against hiades in a turbine with a pressure of about 800 pounds to the square inch.

Simultaneously, the test piece is immersed in a steam hath inside an electric furnace at a constant temperature of 850 degrees, Fahrenheit, identical with the temperature inside a steam turbine at which the steel parts glow a cherry red. To duplicate the often travel around their shafts at speeds exceeding 789 miles an hour, the machine pulls the test piece upward with a force of 9000 pounds by means of levers and springs attached to dead weights.

COMMON RAW MATERIALS GIVE IMPORTANT CHEMICALS

THE world's most important industrial chemicals are made from a small group of mineral raw materials, although the production of a single chemical may require an amazingly large number of other chemi-

cais, processes, and raw materials

If the chemist were given three wishes, as in the fairy tale, he would nick these groups of raw materials: 1, coal, petroieum, and natural gas; 2, suifur and suifide ores; 3, salt, hrines, and sea water. These, with limestone, air, and water are most frequently used in manufacturing our chemical

Drs. R. N Keller and T. T. Quirke at the University of Iliinois have been looking into the source of 150 important industrial chemicals, ranging alphahetically from acetamilide to zinc sulfate. They can he traced back to only 34 raw materials.

Consider ammonia, for example. It and the materials used in its manufacture include ammonia liquors, nitrogen, hy-

Above: Adjusting the "punching " of the machine that tortures teel blades for steam turhines until they fracture as shown at left

drogen, calcium cyanamide, catalysts and catalyst supports, peat, bones, animal ref-use, sugar beets, and the like. Ammonia liquors come from coal gas which comes from coal. Nitrogen comes from the air, hydrogen from water. In fact, all the ammonia sources can thus be traced back to air, water, coal, and limestone.

This digging back into origins is not just an academic exercise. It may very well aid a producer or owner of some raw material to plan manufacturing and dis-tribution of a product. Since transportation of heavy raw materials is costly, in-telligent knowledge of what is needed ultimately to produce a product may allow shifting of industrial plants to more ad-vantageous locations.

Water and air are the most frequently used ultimate geologic raw materials—used 99 and 96 times, in the case of the 150

chemicals. Next in order are coal. 91; sulfur, 88; mineral salt, 75; limestone, 68; tur, 98; mineral sait, 75; limestone, 68; sulfide ores, 32; brines, 24; petroleum, 23; natural gas, 16; saltpeter, 13; potassium minerals, 11; gypeum, 10. The other 21 raw materials are used less than 10 times each .- Science Service.

GLASS-SANDWICH BRICK

A NEW glass huilding block containing an interior screen of glass fiber that sharply reduces the transmission of solar energy was announced recently by the Pittsburgh Piate Giase Company.

The new hiock, developed by engineers

of the Pittshurgh Corning Corporation.

screen in this giass building block reduces transmitted heat

gives a soft, diffused light that reduces glare of the sun. The decreased solar heat trans-fer cuts down the cooling load in air-conditioned rooms. The characteristics of the new glass block adapt it particularly to large areas where softer natural daylight is desirable.

Both the new and the conventional blocks are made by fusing, at high temperatures, two pressed, square glass cups into an all-glass welded unit. In the newer design a fiberglas sheet is sealed between the ble halves, forming an integral part of the finished unit in the center of the block. As in the older design, the high sealing temperature results in the formation of a par-tial vacuum in the block interior when it cools. This increases the insulating value of the unit.

Variations in the effects desired may be Variations in the effects desired may be had by changing the thickness of the fiber-glas sheet. A typical unit of the newer design transmits only 55 percent as much energy as the older block, but 75 percent as much light with a marked increase la light diffusion.

METHYL BROWDE AS

INSECT "EXTINGUISHER"

METHYL bromide, sometimes used as a fire extinguisher, is proving even more useful as an insect "extinguisher" or fumigant, as it will in many cases kill insects without injuring the plants upon which the insects are feeding. Methyl bromide is used—in control of the Japanese bestlo—in the fumigation of fruits

and vegetables from within quarantined areas. It also has been found particularly useful for treating potted plants and nursery stock which may be infested with the larvae of this insect. After treatment the plants can he shipped outside the quarantined area without danger of spreading the pest.

TANK TRUCK FOR LIOUID CO2

NEW model EFH Mack truck recently A placed in service by the Cardox Corp. oration, of Chicago, is an example of the facilities developed by this concern for transporting liquid carbon dioxide at controlled constant pressures and in hulk quantities.

Since CO₂ liquid has a vapor pressure which is dependent upon the temperature of the liquid, the pressure increases as the temperature rises. Prior to this development, hound COs has always been handled in containers in which the temperature of the liquid would become the same as that of the surrounding atmosphere. Pressures as high as 1500 pounds to 2000 pounds could, therefore, result in the small individual shipping cylinders. Containers for high pressure are necessarily of heavy construction so that large capacity containers were impractical and uneconomical.

Cardox transport equipment, such as that mounted on this Mack truck, consists of pressure vessels with relatively low working pressures as, for example, 300 pounds per square inch. Corresponding temperature at 300 pounds pressure is approximately 0 degrees, Fahrenheit. This container is well insulsted so that heat loss will be low and pressure rise in the tank will be slow. The liquid COs is placed in the tank at a pressure appreciably below the working pressure of the vessel, and a pressure relief valve is provided which will open at the normal working pressure of the tank. With the opening of this valve, CO2 gas is bled off from the top of the tank causing evaporation of liquid within the tank, the evaporation prothus lowering the pressure so that the control valve will again close.

This truck unit can maintain constant pressure of 300 pounds over an indefinite period of time by bleeding off approximately

bleeding valve. However, if the truck tank is filled at pressure of 250 pounds, it will re-quire several days before sufficient heat penetrates the insulation to raise the pressure to 300 pounds. A normal haul is of less duration than the time required for the pressure to reach the point where refrigeration by bleeding begins; hence, in actual practice, no loss of gas is experienced in transit. The unit is equipped with a compressor type of liquid pump which enables liquid CO, to be transferred in either direction between truck tank and storage tank and additionally makes it possible to fill high-pressure shipping cylinders and containers.

FLAME-DESCALING

THE operator in the accompanying illustration is flame-descaling an 18,000ound steel casting for a hydraulic turbine. Flame-descaling is a relatively new process for removing the scale from blooms, billets, slabs, forgings, and ateel eastings by means of specially designed oxy-acetylene heating

Flame-descaling a casting with a special oxy-acetylene heating head

heads. The process is based on the principle that when high-temperature is quickly ap-plied to the scale (or oxide skin) on a piece of cold metal, the scale expands and breaks away from the base metal because of differential expansion between the scale and the steel. Descaling has a number of ad-

Insulated tank track for transporting liquid CO, at constant pressure

as pickling, sandblasting, and chipping. The casting shown here, for example, was flame-descaled in one fifth the time formerly required for chipping.

SELF-CONTAINED UNIT HEADLIGHT

ONE of the most significant developments in automobile headlights has resulted from three years of co-operative research and testing by the entire automobile and headlighting industry in colleboration with public authorities. This is

Headlight lens, bulh, and reflector in one unit for most new cars

the new Sealed Beam headlighting system which has been generally adopted for most of the cars to be announced this fall. The new system promises a great increase in safety for night driving for two reasons: the traffic heam is practically without glare; and, second, the lamps are estimated to give virtually their original illumination throughout the life of the lamp.

The new headlamp is unique in that the source of light, the reflector, the lens, and the gasket are all assembled in a single, securely sealed unit. In other words, the headlamp is a single light bulb itself, the parabolic reflector surface of which is allvered on the inside and cannot therefore be affected by dust or moiature. Two types of sealed beam units are available—one entirely of hard glass and the other a composite unit consisting of a metal reflector and a glass lens. The two types will be interchangeable in the recesses provided for them in the newer cars.

These units are relatively more expensive than the present bulbs but, considering the light efficiency as the new lamp ages, the increased cost over ordinary small bulbs loses its significance. Other advantages are that the filament is always definitely and permanently focused for hest results, a wider and stronger country beam is given, while the traffic heam is thrown more sl arply to the right side of the road and gives better to the right side of the road and gives better illumination even far to the right of the shoulder. When the filament finally burns out the whole unit is thrown away and a new one installed.

FOR FUTURE DA VINCIS

ALWAYS a challenge to designers, world fairs have resulted in the development of a number of new architectural forms many of which have later become generally adopted. It is perhaps in the bold use of = 0.8840 =

WHERE SCIENCE ENDS HOSPITALITY BEGINS

The Waldorf, for example, is a magnificent scientific achievement, not only dependent on science when it was built, but continuously dependent on many sciences for the efficiency of its operation.

But every man of scientific turn of mind knows what we mean when we say that hospitality, in his own home no less than in the Waldorf, is something warm, living and human that survives scientific detachment.

And it is that ability to preserve the human touch, in spite of all our clockwork schedules and efficiency, that gives the Waldorf its unique reputation for mantaining close, cordial and communicable contacts with its patrons.

Besides, this year, when you come to New York, you'll get so much science at THE FAIR, that it'll be a genuine relief each day to return to the hospitality of The Waldorf-Astoria!

THE

new materials for decorative and artistic effects that the New York World's Fair, howcer, makes its most striking contribution to the progress of art and design. In this sphere, the Fair has given an impetus to the technological developments of the last few years which may hasten by years their general adoption.

Outstanding is the decorative use of plastics, most notably the brillandity refractive transparent varieties now available. Domenico Mortelluto, for example, has achieved in his mural in the lobby of the De Pont Building, a design remniscent of stamed glass but with a refreshing balance of colors and textures attained by use of the soft and plastic properties of these new materials. The nun-foot cast-phenoine status in the Federal Building, designed by E. H. Burdeck, lighted from within, provide a considerable part of the illumination of the tall plants, whose natural illumination of the tall plants, whose natural illumination strikingly accents different portions of the rounds, are faced with blastic materials.

The use of stainless steel as a scalptural material has been notably advanced at the Fair, as Dr. Gerald Wendt, Director of its Department of Science and Education, has pointed out. Robert Foster, a pioneer in the use of the welded steel sheet, has two gagantic figures in this medium. His winged Mercury," floating in brilliant stantless steel from the wrands roof of the Ford Building, brings out to full advantage the lift, the apparent floating hightness of the speedy mesenger of the good, it his brotic fold of cloth draped over her extended arms. The later mural in the French Paullion

The large mural in the French Pavision by Jacques Durand is done on wood, with synthetic lacquers containing colloidal gold in the focal exhibit in sectione, Allen Saal lurg has used a new technique, painting large transparent murals on gless, using alcohol-soluble dyes applied by the sir brush. Witold Gordon's mural, "Food," is done in rubbe-base paint.

The nex tube lights, lined with fluorescent materials, have rivinled the color of the Fair and are largely responsible for its moctural beauty. Especially striking is the device which sends a vertical beam of light form mercury lamps, set in the sod, upward into the trees. Each quivering leaf glowwith a soft green light resulting from the fluorescence of its chlorophyll. To many, the Fair's heautiful illumnation is its out establing new art form and most memorable with the standing new art form and most memorable D. Luttle. Inc.

DETERMINATION OF

COBALT IN STEELS

In the standard method of analysis of steels and sloys, set to sight hours are required by an experienced chemist for a determination of cobait. By further developments of an electrochemical intration ments of an electrochemical intration company to the second of the second company have made presented as the second company have been second co

In the new method, a sample is dissolved in acid, the cobalt oxidized with a definite excess quantity of standard potessium forricyanide, and the excess determined by titration with standard cobaltous nitrate solution. The amount of cobalt in the sample as calculated from the amount of ferricyanide used for its oxidation.

CAMERA BECOMES A POLICE WITNESS

OFFICER Rollye H. Galbrath of the California Highway Patrol has a positive method of recording the actions of law violators who cross his path in the vicinity of Laneaster, California On the dashboard of his patrol car Officer Galbrath has installed a "robot witness" in the form of a

The camera that pictures speeders Filmo 70 camera that records the action of

the car being "tailed." A photronic cell exposure meter is mounted in a bracket beside the camera.

"You can't argue with a motion picture," is a statement football coaches have been making for years, and in bringing "witness" movies to the police court, Officer Galbraith is pioneering in a field that promises great results.

For definitely proving a case against speeders, why not fasten a second speedometer in front of the camera, so that its dial would appear in a lower corner of the field, with the speeding car visible in the same picture?

IMPROVED SURGICAL SUTURES MADE OF NYLON

N YLON mono-filament is now being used to make surgical sutures. Nylon, the same Dir Pont material that will enter mio fine hosiery, is a man-made, protesn-like usubatance derrord basically from coal, air, and water, characterised by extreme toughous and strength, and possessing the peaking to be formed into filters and allily to be formed into filters and allily to be formed into filters and national coals.

The new sutures have been tested by more than twenty important hospitals and medical conters throughout the country, and declared a marked improvement for dermal sutures. It is said that they are practically non-dritating to the tissues, do not deteriorate is the presence of infection, and

How Mickey Mouse joined our family

by Westinghouse

- "Plastic dishes with pictures of Mickey Mouse—how in the world did Westinghouse get into that line?" asked a buyer. Well, it's an odd story, showing how the logic of production sometimes leads to surprising answers.
- Among the many electrical products that we make are the outlets, switches, plugs, fuses and other
 little connections needed in a wiring system. They are known as
 Bryant and Hemco wiring devices,
 and are made in our factory in
 Bridgeport. In 1928, when the
 amazing possibilities of plastics were
 startling industry, we took over a
 nearby plastics plant to mould these
 various devices.
- The capacity of this plant was greater than our needs, so we either had to cut it down or find new uses for plastics. About that time, scientists created new plastics in vivid, rainbow colors—marvel-ously suited to tableware, toys, smokers' fittings and hundreds of such things. It seemed a long jump from dynamos and motors, but we had the plant and the plastics, so we plunged into the new field.
- Famous designers went to work — skilled tool makers made

hundreds of new dies — we hired salesmen who knew dishes and tumblers rather than switches and plugs —and almost before we knew it, had an important new business on our hands.

- · Our first big hit was with children. They were delighted with fascinating dishes decorated with pictures of Mickey Mouse, Snow White, and other lovable people who live in story books. We have sold millions of dishes glorifying Mickey and his gang! And millions of gaily colored spoons, plates, tumblers and kitchenware, all identified by the well known names they bear -Hemcoware or Safetyware. That ashtray on your desk, the plastic housing of your new electric razor or the beautiful plastic cabinet of your bedside radio-they probably are all of our make.
- Today, this plastics plant is busy with orders from chain and department stores from all over the country...from sales organizations who use these products for premiums and novelties...and from manufacturers who are using plastic parts in their products.
- To us Westinghouse people, trained as we are to do years of research before launching a new electrical product, this overnight success that seems almost to have come out of the air, is startling and effenshing. Actually, of course, it did take a lot of planning and good team work—but still, it's fun to look back and see how Mickey Mouse came to join the Westinghouse family.

because the filament is non-capillary, the possibility of infection penetrating the suture and being carried into the wound is diminished.

Because of the smooth surface of nylon, there is less discomfort in removing the suture from the tissue. The sutures are fast dyed—an aid to the doctor in locating the surgical stitch readily.

LARGE TIRES TO END ALL

LARGE TIRE STORIES

VIGANTIC pneumatic tires that stand J seven feet high-and considered the largest made for actual use are now being manufactured by United States Rubber Company, L. D Tompkins, vice president, announced recently.

The tires are of the size known as 24.00-32, and weigh approximately 1500 pounds each. They are of 34-ply construction, and the rub-

A giant among tires, compared with an ordinary passenger car tire

ber tread at places is more than three inches thick. They comprise the tire equipment on large LaTourneau Tournapull earth-moving machines used by the Guy F. Atkinson Company, of Los Angeles, in building the Hansen Dam near San Fernando, California. These machines are capable of carrying 30 cubic yards of earth at a speed of 17 miles per hour.

Each tire, when inflated-the tube itself weighs 100 pounds—has a load capacity of about 12½ tons. Three men, using a special-ly designed derrick, require five hours to

change one of these tires. Shipping of the tires necessitated the use of open-end railroad cars, as the doors on the ordinary freight and express cars were not large enough to get the tires through.

LUNG COLLAPSE TO

CONTROL TUBERCULOSIS

OLLAPSE of the lung for persons suffering from tuberculosis has been found by the Chicago Municipal Tubercu-losis Sanitarium to be twice as effective a treatment as other measures directed against the control of the disease. A critical study of 7341 cases is reported by Drs. Fred-erick Tice and Allan J. Hruby of the Chicago institution in the Journal of the American Medical Association.

Of title 7341 patients observed, over a

6 1/2-year period, 3090 were subjected to lung collapse for more than three months, 337 for less than three months, and 330 had pneumothorax attempted. The other 3584 patients were controls.

Broadly, the results were twice as good with the treated patients as with the conirols and were better still in comparison with the life expectancy of patients with open tuberculosis as revealed in the medical literature,-Science Service.

SIGHT AND SOUND TOROUG INDICATING WRENCH

NEW type of torque measuring wrench which can be applied to any detachable socket having a 1/2-inch square drive opening, is now on the market. This wrench is of the reversible ratchet type and is designed

to indicate right-hand torque. With a wrench of this type, it is possible for the operator to tighten nuts or bolts even-

Uniform tension on series of bolts is possible with this new wrench

ly and to any desired tension or torque load. Closely limited torque application is now considered essential to many types of automotive, aviation, Diesel-engine and indusirial work.

In application, the wrench may be used by utilizing either the calibrated scale which, by sight-reading, shows applied pressures of 20 to 200 foot-pounds, or by a sharp soundsignal which is given for any desired torque from 35 to 200 foot-pounds. The calibrated scale is read at a point where the index shoulder crosses the scale and the sound signal can be set by a simple device.

Accuracy of the wrench does not depend on gears, levers or dials. Although right-hand torque only is measured, the wrench action reverses for left-hand turning. The 36-tooth ratchet wheel, with twin double-tooth pawl of the reversible ratchet mechanism, makes possible the short operating swing of only 1/36 of a full turn. Wrench action is instantly reversed by a flip of the shifter, located flush with the head.

HIGH EFFICIENCY RAUROAD BRAKE

NEW type of railroad brake which will A bring high speed trains to a smooth, comfortable stop within 2500 to 3000 feet from 100 miles an hour—about half the from 100 miles an hour—about half the distance now required—was announced recently by Edward G. Budd, president of Budd Wheel Company.

The brake eliminates the century-old principle of a metal "shoe" pressing against the rim or tread of the wheel. Instead, the

engineers have patterned the new brake somewhat on those used in automobiles in

Looking backward it is different. This was probably the first time in history that propulson had been achieved and distance occured by means of an internal combustion engine, and the little boat may have been the dim morange star of the motor age. The engine is described by Frank A. Taylor, Caratro of Engineering of the Smithonian Institution, in a descriptive catalog of the Museeum.

Morey's model unfortunately is no longer in essiones. The inventor did not even try to get an American patent on it. All that remains a his description of the device, summarized by Mr. Taylor as a vapor engune in which "a vacuum was produced in the cylinder by firing an explo-ave mixture of air and vapor from common proof-sparits mixed with a small portion of sparits of turn of the properties." A model of this engine ran smoothly for several buns, but there is no record that a large engine was every built.

SUNLIGHT AND

AGRICULTURE

CCIENTISTS in the laboratories of the Jitavaina Sugar Planets' Association in Honolulu are now working on a project which promises to bring the annight factor within the realm of predictability for farming. Their experiments interface that sunlight and its effects upon agriculture can be measured with a faur degree of accuracy. The implications of such a discovery for sarriculture are far-reachings.

The inquiry grew out of experiments which the Experiment Station has long been conducting in the water-absorption rate of growing cane. These experiments revealed that there is a direct and calculable relationship between the intensity of solar radiation and the "thirst" of the rane.

Indeed, so sensitive is the plant to the sun that a mere whey of cloud, passing across the face of the sun, will definitely affect the water consumption of the cane After sundown, as every farmer knows, the water absorption rate of a plant will quickly diminiah. But it is not so generally knows that there are similar changes in the rate of "drinking" during the daylight bours. These changes, it was learned, bear a distinct relationship to the variation in the contract of th

Under the direction of Dr. Harold L. Lyon, head of the Hawaiian Sugar Planters' Association Experiment Station, physicist Hugh W. Brodie has been working on this problem since 1930.

An outgrowth of these experiments has been a parallel study of the possibilities of a large-scale control of trrigation based on sunlight data. This work is now in progress at the Hawaiian Sugar Planters' Association Experiment Station.

The value of such an inquiry may be realized from the fact that, for every pound of sugar produced in Hawaii, a ton of water must be used. Several of Hawaii's larger

in Royal Branza Finish 24 subjects, 35c each, postpaid. SELLRIGHT GIFTWARES CORP. sugar plantations are operable only by irrigation—some plantations using as much as from 50 to 150 million gallons of water

With such a large consumption of water it is clear that considerable attention may be paid to conservation—and profitably, when the expense of pumping and ditching is taken into account. A natural control of sugar cane irrigation through the employment of solar radiation may have broad and far-reaching effects, in savings as well as in increased yields.

NITROGEN

THE nitrogen-fixation process, which recovers that gas from the air for use in our chemical industry and in fertilizers, produces about 4,000,000 tons of fixed nitrogen per year. This amount, however, represents only the quantity of nitrogen over one-fifth of a square mile of the earth's surface.

BETTER MAGNET WIRE

E LIMINATING the need for space-con-suming protective coatings in many instances, Formex wire, a new and superior magnet wire, announced recently by General Electric, is insulated with a synthetic resin which is tougher and more flexible than the conventional enamel coatings

Since Formex wire requires less space for insulation and protection, it gives the designer new opportunities to reduce the size of many products. Further, electrical properties are as good as those of ordinary enameled wires, and tests show that Formex wire is considerably higher in resistance to abrasion and to the common treating solvents. When severely twisted and then subjected to a temperature of 125 degrees, Centigrade, for one hour, ordinary enameled wire cracks but Formex wire is not affected.

It withstands the operations of winding, assembly, and varnish impregnation much

ANOTHER

MATHEMATICAL

PROBLEM

BECAUSE of the interest shown in previous problems, we offer another by Leutenant-Commander Kaplan. Any correspondence relative to this new brain-teaser should be addressed to him in care of Scientific American, 24 West 40th St., New York, N. Y.

The problem: A hole 2 inches in diameter is drilled through a solid cylinder also 2

inclies in diameter, in such a way that the axis of the drill is perpendicular to, and intersects, the axis of the cylinder. What

is the volume of inaterial removed?

The solution will be given in these columns next month. Meanwhile, can you obtain the same answer as the author? His value was 53 cubic inches

better than commercially available enameled wire. It can be used to advantage in nearly all applications where enameled wire has been used, and in addition it can be utilized in many applications to replace enamelcution, enamel-paper, or other fabric-covered wires where formerly a protective wrapping was necessary.

NEW CASTABLE

REFRACTORY

As a result of its recent development work on castable refractores, John-Manville announces a new light weight Fire-crete for making special refractory shapes, for replacing difficult brick construction for lining furnace doors, and for making small monolithic linings. The new product is suitable for working temperatures up to 2290 degrees, Fahrenheit.

Accepted laboratory and service tests.

2200 ougrees, Pantennett as service test we show that the sale state diding to the her of products, widely used by industry for many years, possesses an exceptionally low heat storage capacity. This is of special importance in intermittently operated furnaces, since appreciable quantities of the sale with the sale of the sale with the sale of the sale with the sal

Sixty-five pounds of the material are required per cubic foot of finished construction. It can be used to form any required refractory shape. This is accomplished within a short period of time simply by mixing light weight Firecrete with water and casting it into a form. Twenty-four hours later the shape is ready to be placed in

VERSATILE SURFACE FINISH

SAID to give a hard, flick-proof finish, with perfect adherence to most metals a new urea formaldehyde finish, which is called Ultrakote Synthetic, has been an-nounced by C. W. Haynes Laboratories, Inc. The finish it produces has the appearance of porcelain and is much tougher. It will stand denting, bending, hammering, and general abuse.

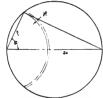

Ultrakote Synthetic can be used on any production metal, ranging from the manu-facture of delicate jewelry to heavy ma-chinery, including the following: metal kitchen cabinets, stoves, refrigerators, ironers, washing machinea, clocks, office machines, and many other applications. can be applied by spraying, dipping, or roller coating. It bakes to a tough, flexible finish at 150 degrees, Fahrenheit, in 30 minutes.

It can be furnished in either water-white clear or any other color, and the "clear" is claimed to be non-yellowing.

SOLUTION OF LAST MONTH'S PROBLEM

AST month, in response to many requests, we published another problem for our mathematically minded readers. Briefly, it was required to find the length of a rope with one end tied to a cow and the other to the edge of a circular pasture 200 feet in diameter. The rope allowed the cow to graze over half of the total area of the pasture.

The solution of this problem, as outlined below, requires the use of the calculus. Reference to the illustration will clarify the symbols used by the author.

The area encompassed by the radius arm o is given by the integral

This may be changed over into an expression involving only the one variable, 6, Since

$$\rho = 2a \cos \theta$$

stitution.

and
$$d\rho = -2a \sin \theta \ d\theta$$
We have, therefore, by making this sub-

 $\int_{2} (2a \cos \theta) \, \theta \, (-2a \sin \theta) \, d\theta =$ -4a' f sin 20 d0

If, for simplification, we let v = 20

dy = 2 d0and the expression for the area becomes

$$-a^2 \int y \sin y \, dy$$

Integrating between the limits

 $\theta = \frac{\pi}{2}$ and $\theta = \theta_0$,

which for y will be $y = \pi$ and $y = y_{ij}$

$$a^{3} \left[y \cos y - \sin y \right]_{\pi}^{y_{1}} =$$

$$a^{3} \left[y_{1} \cos y_{1} - \sin y_{1} + \pi \right]$$

Since, by the condition of the proble this area is to equal one half that of the circle

$$a^{1} \left[y_{1} \cos y_{1} - \sin y_{1} + \pi \right] = \frac{\pi a^{1}}{2}$$

$$\sin y_1 - y_1 \cos y_1 = \frac{\pi}{2}$$

The value of y, which satisfies this equation may be determined by constructing a table such as that shown below, and successively reducing the error of approximation to whatever degree desired.

From this table, it is evident that

 $\gamma_1 = 109^{\circ}11'18''.9$ (very nearly)

$$\theta_i = \frac{y_i}{2} = 54^\circ 35' 39''.5$$
the corresponding value of ρ , using

and the corresponding value of ρ , using 200 feet in place of 2a, will be $\rho_1 = 200$ cos 54°35'39".5 = 115.87 feet

Conducted by JACOB DESCHIN, A.R.P.S.

WHAT POSE?

ONE of the worst bugaboos the nonprofessional photographer has to encounter in his camera work is the selection of a pose suitable to the subject, and one that gets away from the usual thing. Cen-

Figure 1

rally speaking, the head may be posed in one of three principal positions with relation to the camera—full face, these quarter view, and profile. But such a rule as much too wagne, almost too obvious, to be of real use when the purpose is to obtain a portrast that is alive with personality and not merely al likeness, ow that is presumed to he's likeness. Moreover, a true likeness is not merely a physical resemblance, but a character im-

pression.

Posing may broadly be classified in two divisions—the formal and the informal. The formal post formal post is ordinarily associated with the studio or the carefully tranged sensitied with the studio or the carefully tranged sensitied with the studio or the carefully tranged sensitied with the sensitied professional? Portrait type, and which the subject is portrayed in conventional style. Both subject and photographer are conscious of engaging in a rotutine, a sober, methodical routine the end creatify which is the familiar "studio portrait." Not that this type of portrait the pressonality is reteriand; if rited of the subject who see the picture do not quite the personality is reteriand; if rited of the subject who see the picture do not quite recognize the person they know in life.

By contrast, examine Figure 2 and see the difference. This is the subject as we know her, smiling easily and gracefully; vibrant, sparkling, alive. Taken in the studio, also, the method employed was radically different from that used for Figure 1. The subject lighted a cagarette and was allowed to act naturally, to converse and generally to be 'ber sell.' When things booked ripe, ment was caught forever. Figure 2 is as much of a portrait as Figure 1, but which would you vote for 1f you had to make a choice between the two for a prominent piace on your bureas?

Figure 2 is an example of the modern treatment in portrasture, and so are the others reproduced here. Figure 3 is an outdoor shot in the informal manner. A miniature reflex camera was directed from overhead to record a characteristic por and expression, entirely unrestrained and completely at ease. It is easier outdoors to make shots of the informal type with success, partly because of the diffuse and ail-embracing nature of daylight, which permits exposures without having to be too much concerned with light arrangements, partly because subjects seem to be less camera-conscious outdoors. This is one reason why one frequently hears the comment that "the best picture ever taken of me was a snapshot at such-and-such a picnic" . . or boat ride or hike.

or feat rice or mase.

Figure 1 is a many any contrait by Figure 1 is a mean subject, seated on a bench, learned back, restung on her hands and turning her head toward the camera In the final printing it was found that the best result could be achieved by electing the head alone and enlarging that to the final dimensions of the print, and Figure 5 shows how this was accomplished to the great enhancement of the result. Incidentification of the print of the first proved by the simple expedient of deleting the non-seasufish and concentrating on the

Figure

Figure 3

face alone. The angle of the head adds considerably to an impression of liveliness, gayety, movement.

Rules, they say, are made to be broken hut here is one that you will do well to follow: never have the portrait subject facing the camera with both shoulders on a line with the lens. Have one shoulder nearer the camera than the other. When

Figure 4

the subject then turns her head toward the camera, the result will be much more agree-able. Thus, Figures 1 and 4 were posed with one shoulder toward the camera, and Figure 2 with the shoulders at a slight

angle.

The lighting arrangement for Figures 1 The lighting arrangement for Figures 1 and 6 consisted of a main, diffused light, combined with a soft spollight; Figure 2, a spoilight and a soft main light from below, and Figure 3, daylight, with the sun crusiable point peneral oft illumination and a spollight effect. But why is the subject always smilling, one singlet sak? The nanewer to that one it the subject is most characteristically presented in this way. She is at her best

Figure 5

and most revealing when she smiles. Another subject might be untruthfully photographed while smiling, but whether the subject should smile or not is entirely an individual question. One cannot make gen-eralizations; study the subject and record the most favorable and attractive pose and

WHY A FILE?

YOU do not have to have a regular photographic filing device of any kind. I tographic filing device of any kind you may ators your negative in ordinary envelopes and keep them in the bursau. You may ators your negative in cordinary envelopes and keep them in the bursau. This kind of makeshift arrangement may be good enough for 'your purposes. But for those industrious workers who accommisted large numbers of negatives, particularly ghere the negatives vary in size, a somewhat more elaborate system will be found not only convenient but essential. Especially will this be true for the man who intends now and then to dabble in journalistic photography where the shilly to find negatives quickly when needed is

COMBINES THE EASEL AND PAPER STORAGE CABINET IN ONE

Here's an enlarging easel combined with a paper storage box that reduces the movements involved in the en-larging routine to a minimum. The easel is actually the cover of the paper storage box and requires but the lifting of the cover to obtain a sheet of paper

sheet of paper Margins are easily and accurately controlled on this all-metal easel by simply pulling out a lever. The white matte surface facilitates focusing image arrangements Margins are automatically correct and even, with appropriate border. The PAPER (up to 14 x 17 incl. succ) is right in of the easel—available at a second's notice by just lifting the cover.

HERE ARE A FEW OF ITS

- t. Lacks in position the upper edge of the paper, before remaining the hand when locating the paper on the ease! 2 Paper held securely at this stage by spring hinges.
- spring unges. Control by single lever of both upper left carner paper stops, with provision for unequal margins it desired Unlimited widths of white borders from 1/10" to 175" indicated at a glance in scale.
- 5. Opening of frame (A) in advance of member (B) graduated by stap-screw 6 Paper storage, light proof, drawer measuring 15 x 18 x 114
- 7. Non-skid corrugated rubber on bottom.

 Beautiful finish

MAIL ORDERS FILLE

The Prizee Given for the Best Photographs in Each Division will be.

Five Hancrable Mention Awards, such cancisting of a sne-year subscription to Scientific American

Remember that these prizes are to be given in each division—or a total of six watches and six enlargers totaling \$137.38 in value, including the 18 subscriptions to Scientific American

*Watch wingers may make their ewa esjection of neoket style or sentiamen's ar lady's wrist watch.

The contest will be judged in three divisions, as follows: Division .i. Human — including portraits and other camera studies of people

vicion 2. Landscapes—including i scanic views, closs-ups of parts landscapes, nesscapes, and so

Division 8. Action—including all types of photography in which ac-tion is the predominating feature.

First Prizs One \$250 "Lifetims" LONGINES WATCH

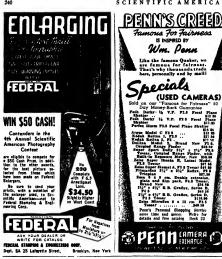

Third Prize

Ons FEDERAL #836 VARIABLE PROJEC-TION PRINTER (List Price \$29.50)

Second Priza

One \$125 LONGINES WATCH

Fourth Brite Oss FEDERAL #120 ENLARGER (List Price \$17.95)

of the utmost importance. The lack of a good system may frequently mean the dif-ference between a sale and a missed opportunity to cash in on one's hobby.

FLOWER CLOSE-UP

FOR rendering details in flowers, the I close-up supplementary lens is fre-quently employed to advantage. The picture of hollyhocks reproduced here, for example, was made with a miniature reflex equipped

"Hollyhocks"

with a proxar supplementary lens which permitted an approach to the subject much closer than that possible with the unaided lens. Incidentally, the picture shows the flower in several stages of development, from the closed bud onward. In the present instance, some foreshortening may be seen in the near petals of the largest blossom, although it does not appear to be objectionable

FIFTH ROCHESTER

INTERNATIONAL SALON

ENTRIES are now being invited for participation in the Fifth Rochester International Salon, to be held at the Rochester Memorial Art Gallery, Rochester, New York, from January 15 to Febru-ary 25, 1940. The closing date for the submission of entries is December 14. Entries are divided into commercial and pictries are divided into commercial and pic-torial groups. Fee is \$1 which includes the right to submit to the maximum of 6 colored lantern alides, 4 monotone prints, 4 color commercial prints, and 4 color pictorial prints.

VIEW CAMERAS

IN DEMAND

RECENTLY we have been noticing a considerable revival of interest among amateurs in the use of the view type camera-Particularly does this seem to be true of the 4 by 5-inch view, such as the Kerons and the newly introduced Crown. Secondhand view cameras of this type that appear hand view cameras of this type that appear in the stores do not seem to stay very long and one frequently hears favorable com-ments concerning the use of a type of cam-era that has usually been associated only with professional studio workers. While the

view camera, even the 4 by 5, is limited because it has to be used on a stand, many find it ideals for indoor portrature and other subjects; even landscapes. The 4 by 5 size, the "minasture" of the 8 by 10 and 11 by 14, is easily carried in a small fiber case, together with the necessary film holders and so on.

PHOTOGRAPHING THE

A WALK in the park for the express purpose of making a photograph of Sandy offered an unforeseen problem. Sandy was obedient enough and would stay in one place for minutes at a time, but he seemed

to be fraghtened at the sight of the camera and would not behave normally Sometime-be cowered; at other times he was higher and nervous. One of the difficulties was getting his ears to stay up. This was finally secomplished, after many attempts, he vomore standing just behind the photographer and, by one sign and another, convincing some standing behavior of the state of the stat

THE CAMERA SISSY PHILOSOPHY

PERSONALLY, we like to buy a cannorin a brand new condition, never handled before outside the photographic store. We have been the feet of the property of the tear according to a manner has come as a result of having been handled and used by us in the course of our picture-making activities. As time goes on and the camera assumes a worn condition it is comfortable to know that it became so because we had used it frequently. The camera, by these sentant of wear becomes associated with our personal experiences and the pictures we made with it.

We smit that, like other camera mers, we desire occasionally—and, when we can afford it, fulfill the desire—to trade in our camera for a now one, one equipped with the newer gadgets. They are hard to resist, these handsomely contrived, new camera models, not only because they are good took at but the few gadgets are real improvements and signify advances in camera'd design. Nevertheless, no matter how

BETTER PICTURES WIN PRIZES

and

"SO YOU WANT TO TAKE BETTER PICTURES"

By A. P. PECK
Associate Editor, Scientific American

IS THE ONE BOOK

that shows you, simply and in understandable language, how to take the best pictures under all conditions.

"Pictorial appeal and technical excellence" are yours for the choosing when you map the shutter. You must first, however, be familiar with certain fundamental of composition and camere operation. These fundamentals are difficult to dig out of the average book, but not when you have a copy of "So You Want to Take Better Pictures" at hand. You learn as you read, easily, pain-lastly, without having to weds through a mass of material that holds no immediate interest.

Written expressly for those millions of camera owners who have their developing and printing dons at the photo shops, the lessons which it teaches are simple and straightforward, uncomplicated by formulas and directions meant only for the darkroom fan.

Buy from Dealers - Write for Folder J. H. Smith & Sons Corp. Griffith, Indiana long or how short the period during which a camera is actually in our possession it was a new one when we bought it and that, for us at least, is important.

There are persons, however, who look upon this camera sissy philosophy with disdain. They prefer an old camera, a used camera, and they don't care how many people had used it before they took posses sion. A camera is a camera, they say, and what's the difference so long as it works? Well, that's one way of looking at it, and maybe we're wrong. But we know that many people agree with us and would rather save up the few extra dollars required to make the sum asked for by the dealer than to buy an old camera now, because they do not have the few extra dollars, for the mere sake of ammediate acquisition.

BOOK PLATE

SUCCESTION

ME backlighting of the leaves and the simplicity of the arrangement were the things that attracted us to the subject of the hanging rambler branches. A red filter was used for the sky and the moment was awaited when the cloud mass moved along

Design for a bookplate

into the desired position behind the subject. Because of the near view, the clouds were naturally rendered very soft-edged so that the purist might object to the picture on this account, declaring that the clouds have too much the appearance of a piece of cot-ton pasted in the aky. However, clouds do not always have to be rendered sharp. One does feel, however, that the picture is somedoes feel, however, that the picture is some-how incomplete. A solution that immedi-ately comes to mind is the use of the print for a bookplate, with the usual wording lettered in the roomy space in the lower left part of the print.

CARRYING FILTERS

Profitable Photography with the

Miniature Camera

By Edwin C. Buxbaum, A.R.P.S.

BESIDES having a considerminiature camera, making trick "shots," art photographs, and the like, you can also use it for special paying work. This little paper-bound booklet of 72 pages tells not only how to make interesting photographs that are salable to news agencies or magazines but also gives many clues to the very large number of types of photographs that can be sold. For those who wish to mix profit with pleasure this booklet should prove most helpful.-\$1.10 postpaid.

For sale by

SCIENTIFIC AMERICAN 24 West 40th St., New York, N. Y. to be scratched or broken. You should be as careful of these as you are of the camera lens itself, for it must never be overlooked that the filter or supplementary lens is placed over the taking lens and that any damage suffered by these elements will have its effect on the negative.

WHAT'S NEW

In Photographic Equipment

If you are interested in any of the items described below, and cannot find them in our advertising columns or al your photo-grophic desire, we shall be glad to tell you where you can get them. Please accompany your request by a stamped emotopy.

Zeiss 6 by 6cm Ikoplex III (\$199): 21/4 by 214-inch swin-lens reflex camera equipped with Carl Zeiss Tessar //2.8, 8cm

(31/6 inches) Spring pressure plate assures film placement in focal plane of lens. Tessar matched with //2.8 finder lens of same focal length, projecting image of subject on plano-convex focusing screen. Illumination uniform over entire

screen area. Four-times magnifier covers enscreen area. Four-times magnified covers en-tire focusing screen. Quarter-turn wheel focuses four feet to infinity. Scale on focusing wheel shows depth of field. Albada eye-level finder in which front element tilts forward and back as lens is racked out and in, correcting for parellax at all distances. Operating lever, with one smooth movement, simultaneously winds both film and shutter. Counter dial shows number of exposures made. Half-turn of lever advances film, spacing negatives evenly and winding shutter with one motion. Shutter is Compur-Rapid with speeds from 1 second to 1/400, bulb and self-timer. Signal shows whether shutter is discharged (black), wound (red), or set on self-timer (white). Sbutter release adjacent to operating lever. Shutter speed and lens aperture settings controlled by levers on each side of shutter and visible in separate win-dows on top of camera. Double exposures and skipped frames eliminated by coupling of film-transport and shutter-winding mechanism. Tripod socket accepts standard American screw. Eyes for carrying strap. Standard 37mm slip-on filters and lens shade, as well as new Zeiss Ikon 35.5mm screw-in filters, fit lens. Film is loaded in usual way, then advanced until arrow (on paper leader of all film) lies between white dots on inside of camera. Hinged back is then closed and automatic counter mechanism goes into action

Hrus Optrica, Sinne Rruz (\$1.50) · Made of engraved tainless seel. 6. 1/2 inches of engraved tainless seel. 6. 1/2 inches long by 1 inch wide by 1/8 of an inch thick, this rule gives photographers necessary information about lenses, focal lengths, magnifications, and measurements. For example, rule gives depth of field obtained when focal length of lens and perture are known, assuring sharp enlargements of great djameter. Rule also contains, conversion tables—fahrenheit to centifgrade, ounces to cc, mm to inches, grains to grams.

"Curves and Clouds," by Frank A. Richardson, with an Auto Rollerflex . . . 1/100 second at F/8

Composition is Easy with a Rolleiflex

E YEN the beginner will find it easy to make sharp, well-composed pictures with a Rollei camera. For composition, as well as focusing, is done on the ground glass screen. You see each picture as it is going to appear in the finished print. There's no parallax—no view finder—no range finder through which you have to squint. And the extra fast finder lens (an exclusive Rollei feature), renders a brilliant image even when the camera's lens is stopped 'way down to 11, 16 or 22.

Moreover, you get pictures of a practical size—twelve negatives $2\frac{1}{4}$ " x $2\frac{1}{4}$ " on a roll of standard, easily obtained 120 or B2 film. Makes beautiful Dufay-

color shots. Kadachrome cut film or 35 mm. rolls may be used with special adapter backs which are quickly attached.

There are now five different models from which to choose, priced as follows:

\$77.50
Rolleicord Ia, Zeiss Triotar f/45 lens in Compur shutter

BURKE & JAMES Inc

JACOB DESCHIN, conductor of our "Camera Angles" department, will answer in these columns questions of general interest to amateur p hotographers. If an answer is desired by mail, enclose a stamped, address envelope. Queries should be specific, but Mr. Deschin cannot undertake to draw comparisons between manufactured products nor to advise on the purchase of equipment or materials.-The Editor.

Q. I would like to get a picture of the moon, using a 3-inch refractor made by Bausch & Lomb prior to 1900. The objective is clear and I would use a 1-inch eyepiece. It is my underatanding that if I should use a camera, it would be used simply as a film holder and the lens would be removed from the camera. I would like your advice as to the mechanical arrangement of the equipment; also as to the type of film to use .- J. C. C.

A. The procedure sometimes employed is to remove the eyepiece of your telescope and attach in its place the lightest ground-glass camera you can find. The camera lens is removed and focusing and exposure is done as normally. Very fast film, such as Super XX or Superpan Press is required and an exposure not exceeding one half second.

The correct focus must be found by trial and error because astronomical telescopes are corrected for the visual, not the chemical (photographic) rays. This experimentation is done as follows: Focus with the eyes as usual, getting the image as sharp as post Now, moving 1/16 of an inch at a time, rack Now, moving 1 to or an incident at a time, the the film plane forward, making an exposure each time you have moved the film plane to a new position. Develop the negatives and study the resulting pictures, from which you can select the one that appears to have heen focused the most sharply Mark the point of correct focus in some permanent way so that all you will have to do in future is to set the film plane at this point without further focusing. Incidentally, the negatives will provide a test of the required exposure. If the negatives are too dense, this will mean that a shorter exposure than one half second

that a shorter exposure uses use and a may be given.

Another method, using a reflecting telescope, is described by Harold A. Lower in his article on "Celestial Photography" in "Annateur Telescope Making." The image of the moon as the focus of a six-inch misror," writes Mr. Lower, "will be about half the control of the moon as the focus of a six-inch misror," writes Mr. Lower, "will be about half the control of the moon and the control of the control o an inch in diameter, but it is so bright that it may be magnified by an eyeplece to about an inch, and still be bright enough to an men, and sum pe origin emough to photograph with an exposure of less than a second. Use an eyepiece of about one-inch focus, and project the image of the moor on a sheet of ground glass. Determine the distance from the eyepiece which is

required to produce an image one inch in diameter. Then make a box to mount over the eyepiece, which will hold a plate-holder or ground glass focusing screen at the proper distance. There should be a door in the side of the box, so that one can adjust the eyepiece until the image of the moon is sharply focused. A small reading glass is quite a help in determining when giase is quite a neip in determining when the image is the sharpest. When the focus is the best obtainable, replace the ground glass with a plate-holder. Have an assistant glass with a piate-noicer. Fixee an assistant hold a sheet of black cardboard in front of, but not touching, the telescope. Then re-move the slide of the plate-holder, look through the finder and make sure that the telescope is centered on the moon. exposure is made by moving the cardboard exposure is made by moving the cardboard edgewise from in front of the telescope, snd replacing it as quickly as possible. Be care-ful not to jar the telescope. If the exposure is short enough, the motion of the moon will not be rapid enough to cause a blur, even if the telescope is not equipped with a clock For further details we suggest you consult the article, which appears on pege 254 of the 4th edition of "Amateur Telescope Making."

Q. I have a camera with f/4.5 lens. Unfortunately, there is a nick on the rear element. Due to the fact that no branches of the German manufacturer are in New York, I am unable to have the lens polished. Do you know of an optical concern which will polish it? Also, if worse comes to worst, under what conditions would the nick be the least discernible on the negative? That is, should I attempt to fill it with Canada Balsam, or blacken it to avoid reflection?-T. F.

A. Although there is no manufacturer's "branch" in this country, the importer of your camera can undoubtedly help you.

Concerning your last question, Arthur Lockett, author of "Camera Lenses," s standard work on the subject, advises that "a cracked glass may not impair the per-formance of the lens unless the outline of the crack is, so to apeak, markedly priematic or irideacent in effect." Even then, he suggests that the lens may be made to work astisfactorily by painting a narrow line of opaque black varsish around the crack or

- nick. "This most probably will not above at all on the screen," he adds," and will only subtrast infinitesimally from the amount of light. Similarly, a broken lene say be comented, preferably with Canada Balasan; but if this is difficult, the "Diamond' coment used for mending china, etc., will answer, or even a strong, hot gelatine solution." We would suggest you make asveral exposures with your lens as it stands and carefully examine the resulting negatives; if you can detect no real fault continue to use the lens as it is. Otherwise, ask the camere importer to recommend a good lens repair firm.
- Q. Occasionally I have to turn out a large number of prints and profer to keep them all in the wash water until I get through with the ontire batch. This may take several hours and the first prints will therefore have to stay in the water all that time. Will excessive washing hurt the prints?—L.K.M.
- A. Excessive washing sometimes causes frilling. An effective preventive that has been used with large prints, such as photomurals, that have had to be left in wash water overnight, is to add to the wash water about 5 percent of sodium bisulfits.
- Q. Please advise what model or number motion picture camera made by Eastman would be most suitable for a beginner—also projecting equipment.—T. S. C.
- A Queries concerning the equipment of a particular firm should be addressed directly to that firm as they are in the best position to give advice concerning cameras and equipment of their own manufacture. Accordingly, we have forwarded your inquiry to the Service Department of the Eastman Kodak Company.
- Q. I have heard it said that when photographing at high altitudes, it is necessary, because of the increased brightness of the light, to decrease the normal exposure. How much shorter should the exposures be?—S. E. L.
- A. That depends on the altitude. For a general example, at 2500 feet, give three quarters the normal exposure; at 5000 feet, two thirds; at 10,000 feet, one half, and at 15,000 feet, one third.
- Q. In developing roll film in a tray by the sec-saw method, I frequently have trouble in getting the film into the solution evenly. Can you suggest a remedy?—W. B.
- A. Simply immerse the film in water before starting development. This will have no effect on the latent image but will make the film limp. Developing will then be even and you will avoid the possible danger of having air bubbles form on the film.
- Q. I would like to study photography, especially motion picture work. Will you please suggest some schools? I would also like to knew what company sells motion-picture equipment.
- -S. C. A. Two schools which have special departments for the study of motion pictures belongraphy as the New York Institute of Photography, 10 West 33rd Street, New York, New York, and the American School of Photography, 5501 Michigan Arenue, Citagon, Illiands. Both schools offer resident and correspondence courses. A card

addressed to the schools will bring literature and complete information.

Motion-picture equipment may be purchased in practically any photographic any ply house. Some of these companies are listed in our advertising columns. They will be glad to send catologues and prices if you will write them.

- Q. Do you'know where I might find a table showing emulsion speeds of various films recorded in both Din and Weston, or a table to convert Dir readings?—W. W. M.
- A. In the United States, film emulsion speeds are rated either in Schenner or Weston. Din ratings are used in Europe. A conversion table that includes American Schenner (as distinguished from European Schenner (as in Industrial in Practical Speeds Films and Plates). It is of film that the American Mesion, Din, and Elasto, a list of film and Plates. It is of film that the American is the second speed of the Speeds (as Industrial Industri
- Q. I have an old 9 by 12cm Bakelita film-pack adapter in which the grooving has broken off, causing light leakage. I understand that it cannot be repaired. What would you advise?—A. H. W.
- A. Since the adapter was molded in one piece, special growing machinery would be needed to put it in working order again and this is obviously out of the question because of the cost involved. The only remedy is to have a repair man fit a 3½ by 4½ kit into the broken adapter. While the size of the negative is thus reduced, the difference is rather slight.
- Q. Can you supply a formula for making a gum similar to that used on postage stamps which I can apply to the backs of small prints and which will need simply to be moistened before use?—H, C. M.
 - efore use?—H. C. M.
 A. In five ounces of heated water, stir:
 10 ounces of fish glue or liquid glue
 - 5 ounces of liquid glucose 5 ounces of denstured alcohol

Few drops of carbolic acid

Thin the resulting solution with water to
the desired consistency and brush the backs
of the prints. If the prints are to be trimmed,
apply the gum before trimming and trim
after the gum has dried.

- Q. I am undecided whether to purchase a camera taking only roll film or one equipped only for filmpack and cut film holders. Can you give pros and cons as to which is more advantageous, roll film or filmpack?—
- activating costs, rott time or impacts are activated by a fill produced than roll film, although with practice the than roll film, although with practice the than roll film, although with practice the thin roll film is caused to loaded almost as quickly; furthermore, the roll-film type of causes requires opening the camers to load. Roll film is easier to develop because an entire roll may be developed at the same time. In the case of filmpacks the films have to hendfeld individually, although tanks are available for developing them all at most activation of the roll films and the roll films are the films of the roll films and the roll films. The roll films are roll films and the roll films are restored are for foundation than still films.

Super DOLLINA

Have is the latest streamlined addition to the popular line of Poillins 25 mm miniatures. It is remarkably fluit in add compact, which is a preclaim many features in a built-in range disder—leaves represented and optically perfect properties on the spill-image principle. All control parts are remarked to the properties of the spill-image principle. All control parts are in the properties of the spill-image principle. THE GLASS GIANT OF PALOMAR

By David O Woodhury

TAINLY this most readable book con-MAINLY this most readant contelescope, what went on behind the scenes within the broad circle of scientists and engineers who conceived it, planned it, gradually evolved its details and then built it The swiftly moving narrative begins with Hale, the prime mover, and proceeds steadily down through to the present year (completion of dome and of mounting, grinding and polishing of mirror up to final parabolizing). For two special reasons it is authentic: first, the author, an outstanding contributor to first-rank magazines, is a telescope maker, hence closely comprehends his subject; second, he spent long periods at the site on Palomar and at the California Institute of Technology, also living with those who designed and are making the telescope, and set down their oral accounts in lively style. They also checked the book for accuracy He also scoured the country from end to end in search of every root from which the telescope has sprung. Very much of the text consists of personal narrative within quotation marks revealing the actual dealings, the daily give and take, and the differences and compromises of the principals. The book, though largely about people, does not skip the scientific or engineering detail of the huge undertaking. Thus it answers both the personal and astronomical ques-tions which outsiders have often asked in vain. (380 pages, 61/4 by 91/4 inches, 66 illustrations.) - \$3.10 postpaid. - A. C. I.

THE SCIENTIST IN ACTION

By William H. George, Ph.D., Royal Society Research Fellow, Lecturer in Physics, University of Sheffield

ROM this book the thoughtful, studious reader may obtain a picture of the cientific method in some of its most searching, rigorous aspects and see how the scientist applies it. Not an elementary book. (354 pages, 5½ by 8½ inches.)—\$3.10 postpaid—A. G. I.

COMPOUNDING IN THE ENGLISH LANGUAGE

By Alice Morton Ball

I S it all one word, two separate words, or is it byphenated? Worst bugbear of writing in our illogical English language is word compounding. If you think that even editors understand It, watch any two of them fight. Everybody tears out hair, however, about compounding. Here is a book con-103-page alphabetical list of nearly 13,000 of the word compounds that cause the most trouble, worked out by an author who has prepared the writing style manual for the U. S. Department of State. When in doubt, you flip it open and there is your answer Also, for those few who want really to learn the principles of com pounding, there is an exhaustive study of the underlying basis of the whole matter (226 pages, 6% by 9½ inches.) -\$2.60 postpaid - A. G. I.

MAN MAKES HIMSELF

By V. Gordon Childe

N which a noted British archeologist presents an account of human progress from the Old Stone Age, without inflicting on his readers the technical terminology and jargon of the specialist. He describes three great revolutions in human history—the Neolithic, the urban, and the recent revolution in knowledge. (275 pages, 5 by 8 inches, 11 illustrations.) -\$2.60 postpaid .- A G. I

ESSAYS FOR THE STUDY OF STRUC-TURE AND STYLE

Ry Leo E A Smille

ONE of the largest industries in America is that of writing for publication It is said that everybody is writing a novelor something. This collection of essays with its lengthy discussion of types and style of writing and its discussion of grammatical questions is intended as a guide for these writers. As such it may be highly recommended for slow and careful reading. (717 pages, 51/2 by 8% inches.) -\$2.35 post-paid.-F. D. M.

THE PROPERTIES OF GLASS

By George W. Morey, Geophysical Labora tory, Carnegie Institution of Washington

AS Nature pathy put it, "an eminently scholarly and exhaustive monograph which is bound to be of immense value to the wide circle who have to do in some way or other with glass." Chapters treat re-spectively the history and definition of glass, devitrification, composition, chemical durability, viscosity, annealing, surface tension, heat capacity, heat conductivity, den-sity, coefficient of expansion, elastic prop-erties, strength, thermal endurance hardness, optical properties, electrical conductivity, dielectrics, magnetic properties, constitudefinitely technical. A veritable storehouse of very compact, solid, dependable informa-tion on which the author, a member of the staff of a laboratory which has given much attention to glass since the World War, has been diligently at work since 1924. (561 pages, 6 by 9 inches, 20 illustrations.)— \$12.60 postpaid.—A. G. I.

THE MODELMAKER

Volume 15

A YEAR'S issues of The Modelmaker magazine bound in permanent form, of particular interest to the hobbyist who has a well-equipped sliop and is sometimes at a loss as to what project to start next. It is particularly concerned with advanced work in such things as the construction of model railroad equipment, model engines of various types, and improved equipment for the home shop (210 pages, 7 by 10 1/2 inches, well illustrated and indexed -\$2.00 postpaid A. P. P.

PROJECTION PRINTING WITH THE PHOTOMETER

By A I Haynes

E XPOSURE in projection printing is a stumbling block for many amateur photographers. Without correct exposure it becomes impossible to obtain the finest possible quality from the negative. It is because of this stumbling block that exposure meters for enlarging have come into rather wide general use in recent years. To guide the photographer in the use of these meters, the author of the present book has prepared what might be termed a manual for this particular phase of photographic endeavor. The chapters deal with exposure meters, paper speed ratings, negative density range, paper exposure scale, and so on. (48 pages, 5% by 8%.) -\$1.10 postpaid.-A. P. P.

ABOUT PETROLEUM

By J. G. Crowther

W HAT petroleum is, where it comes from, where it is obtained, and how it is processed, is the scope of this book written for the motorist, aviator, mechanic, business man, and others, by a technically trained writer who treats the subject neither lightly nor very technically. (181 pages, 5 1/2 by 8 1/2 inches, 24 illustrations.)— \$2.35 postpaid .-- A. G. I.

THIS EARTH OF OURS

By Victor T. Allen, M.S., Ph. D.

EITHER as a readable textbook or a somewhat textbookish popular work, this treatise covers geology, both physical and historical, in a scientific manner, the

HANDBOOK OF CHEMISTRY AND PHYSICS 23rd Edition

Edited by Charles D. Hodgman

NUMEROUS additions and revisions make this 1939 edition of a familiar reference even more valuable than its predecessors. Important additions are tables of Melting Point Index and Boiling Point Index of Organic Chemicals. The tables of Physical Constants of Inorganic and Metal-Organic Compounds has been thoroughly revised. The page size of the volume has been slightly increased over that of former editions, giving the book hetter proportions. (2221 pages, 41/2 by 7 enches.) -\$6.10 post-paid -L. B. P.

BACKGROUND TO MODERN SCIENCE Edited by Joseph Needham and Walter Pagel

TEN British writers—Dampier, Ruther ford, Bragg, Aston, Eddington, Ryle, Nuttall, Haldane and other outstanding secentials-lectured at Cambridge University on physics, astronomy, physiology, parasitol ogy, tropical medicine, evolution, and gen-cities, presenting these subjects historically (mainly, however, reviewing advances during the past 40 years slone). These are the lectures. Informative reading. (243 pages, 51/2 by 8 inches) -\$2.10 postpard -A G. I.

CASEIN AND ITS INDUSTRIAL APPLICATIONS

By Edwin Sutermeister and Frederick L

WHATEVER the chemist wishes to know concerning the chemistry and uses of casein will be found in this very complete study. It discusses and explains in detail for the chemist interested in plastics the background facts in the use of the milk product, its manufacture, testing, analysis, storage, and its use in plastics, glues, paper making, paints, the leather industry, medicine, and other applications Extensive bibliographies and references to articles are given (433 pages, 61/4 by 91/4 inches, numerous illustrations.) -\$6.60 postpsid.-F. D M

FASCINATING FAKES IN

PHOTOGRAPHY

By Marcel Natkin, D.Sc. SHADOWGRAMS, smears, screens, bas-relief, photomontage, distortions, infra red—the text runs the whole gamut of photographic tricks that can he accomplished by the average amateur photographer who does his own processing. Many of the effects described are old, in the photographic sense, but they are so we'll epicted and so thoroughly explained that the book represents genuine value to the serious-minded camera fan. (72 pages, 7 hy 11 inches, thoroughly illustrated with a large number of photographs and diagrams.)—\$2.10 postpaid.—A. P. P.

TELESCOPTICS

A Monthly Department for the Amateur Telescope Maker Conducted by ALBERT G. INGALLS

URKING in the rearmost cell of the average amateru telescope maker's brain is the hope that someday he may work up to a full 20" reflector, and a number of telescopes of that size are known to be in the making. The cleance of the control of the c

Figure 1: 2200 pounds of trim telescope

flector shown in Figures 1, 2, and 3 was built by William Buchele, 2832 Sagamore Road, Toledo, Ohio, who pervously had made two smaller saces. Modesly, Suchele at first sent in magazine but one small photograph accome. The instrument shown by that photograph looked so good that he was rivited to put modesty ande and write down the details about this telescope, ance these will be of value to other amateurs who plan telescopes of this size.

"Your letter," he replied, "puffed me up a bit and, if I do any bragging, it's your responsibility. I started telescope building about three years ago, using a borrowed copy of the first edition of 'Amateur Telescope Making.'

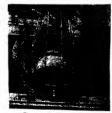

Figure 2: The Porter split ring

That's when my trouble started, and I haven't been the same since. After making the two smaller instruments I ohtsind a 21" Pyrex disk weighing 100 pounds and, at the end of about 40 hours' work, I had it roughed

end of about 40 hours' work, I had it roughed out to 1/5. Fine grinding took six hours, polishing nine. The was all done by hand, the 100-pound murror face-down over a full-aized tool and polisher, and I would not advise any one to attempt this unless he has an elephantine physique, [A. W. Everest also did the —Ed.]

"Figuring was done with small tools, mirror face-up. The correction is within 1.5 percent of a full paraboloid and the figure is smooth and regular, the performance good.

"Both the convex secondary and the diagonal flat are of Pyrex; I turned down 8" diaks to 6½" to gain extra thickness. In correcting the convex I used Hindle's method, and a sphere to figure the flat.

"Hindle's 18-point flotation system (Figure 4) was also used to support the mirror, though I doubled its number of inner edge supports. Figure 4 also shows the outer edge support shoes. The cell is a combination of steel plate and castings, welded, as is the lower part of the tube.

"The lattice-type tube (Figures 1, 2. 3) is bolted to the solid part. Its

Figure 3: Octagon hoops and spider

eight pieces of tubing are of 1½" dissurer, 23-page vall, odd-rolled steel. The 3/16" its rods and the perforated octagon hoops also are cold-willed steel, the latter (Figure 3) being made of 16-gage channels. A ½" washer was brazed into each corner of the octagon and the tubes were then presend through these bloss and brazed, makpressed through these bloss and brazed, makwhich the tube rests. Figure 2 best shows the pairs of additional tube breess stretched

Figure 4: Cell. Flotation system

over the squared ring at the top of the solid part of the tube. These give added rigidity I can detect no flexure by visual inspection of the mirror reflections.

"For the spiders (Figures 3 and 5) to support the secondary murrors I used saw-blade

"The dechnation axis trunnions (Figures 1, 6, 7) are castings of special material, (cast iron, nickel steel), as are the four other large parts of the mounting. All were normalized before mochinies. I under my applications of the mounting
before machining. I made my own patterns
"As I own no lathe or drill press I was
forced to have the lathe and similar work
done outside.

"The declination bearings are used truck ball bearings (radial thrust, 5" O.D.). They had to be large because the trunnions were to be hollow to allow the reflected rays to pass through to the eyepleces.

"I placed the declination circle with its shielded light (Figure 6) on the west side. It is divided into half degrees. The index con-

Figure 5: Lower spider, Cell, Prism

Figure 6: Declination circle. Eveniece

sists of a bright copper wire. On the east side is a reversible slow-motion motor with gearing (Figure 7), mounted on rubber. A small clutch allows this axis also to be moved manually without adjustment or disengagement of gears.

"For the south polar axis I used a radial thrust, self-alining type of bearing (Figure 8). The bearings under the split ring (Figures 2, 3, 9) are used auto parts. The inner race is stationary, while the outer race rotates under the big ring. This gives a fourpoint support, spread over a large part of the ring. Each pair of rollers is pivoted, and this tends to cancel out possible irregularities on the bearing face of the ring. "The RA. setting circle (Figure 9), is

divided into minutes.

Figure 7: Dec. slow motion motor

"The principal gear train for the drive in R.A. has a 1/8 H.P. synchronous motor (Fig-ure 8), mounted on sponge rubber. Slow motion in R.A. is obtained by a reversible motor operating through a clutch, as in the declination axis drive. This is mounted on the under side of the large worm wheel beneath a side of the large worm wheel beneath a housing. The large circular object in Figure 8, near the worm wheel, is a guard to protect

the gear, also the clothing.

"A 2½" prism, shown dimly beneath its cell ring and above the spider in Figure 5, is used to direct the image to either of the eye-pieces at the respective end of the declina-tion axis, simply by turning the priam cast or west one half turn. Very construction ob-serving position is thus made possible. "As a finder turn of the construction of the rotathle tube (Figure 1). "My coherentory (Figure 10, 11) was made by adding if to our garage. The telescope rets on place (Figure 12), with footing if deep. The observatory facer is 6½ shows the used to divert the image to either of the eye-

THE BEGINNER'S CORNER

IITILE ways of doing common, operations, downed and used by different workers, are extremely numerous; escaredly any two doe a job alike, in fact. Ed. C. Rizzo, R.F.D. I, Cold Spring, Ky., tells how he makes laps. In a wooden mold I? wide, 24' long, 36' deep, lined with wax paper, he peels the paper of and, in a warm rown, cuts the strip into I' squares. Each of the four aides of each againer is then cut with a reunder of each againer is then cut with a re-

entrast curve, the result being a prepared facet, shaped like a four-pointed star. These are attached to the warmed tool with terps. The object of the star-shaped facets is that, after cold-pressing and swelling out, such a shape becomes a source; while a square, as commonly used, tends to become a circle. Whether a lay made of squares is superior to one made of circles is a separate question.)

To make a pitch lap free from bubble holes, Edward Lenard, 4835 N. Austin Ave. Cheago, heats the pitch in a double both stirring it often; then removes the inner receptacle and holds it 6" ahove a low flame until the pitch is thu enough to pour readily, surring all the while.

TELESCOPTICS (Continued from preceding page)

garage floor and is 11' square, grying ample room. The housing for the telescope rolls off on a gantry (Figure 10), and is so compact that, when closed, it is scarcely noticeable from the street.

"The sidereal clock (Figure 13) was made from an ordinary pendulum clock. For the pendulum I substituted a longer and compensated pendulum, thus reducing the speed of the hour hand to one revolution per 25 hours. On the dial face is a star map, and stars at the zenith are indicated at all times by the hour hand.

"For the benefit of any faint-hearted apprant for a 20", you may say that I am not an engineer, neither am I a mathematician my school training was very elementary.

"Our local Toledo Astronomy Club is an

the June, 1939, Astrophysical Journal, Robley C Williams of the University of Michigan, after questionnairing 16 observatories, states in an 11-page article that "the most probable useful life of a coating of either of the films is from 21/2 to upward of five years, depending upon the excellence of the coating, its care, and the degree to which it is subjected to condensed moisture and dirt particles.

lu the July number of the same journala professional astronomer's journal than which there certainly is no whicher-occurs the statement that the new Skilling and Richardson "Astronomy", reviewed in Scientific American for August, is "the best single book available for teaching a large amount of astronomy to the uninitiated student," in flattering agreement with our own review.

Dave Woodbury, a T.N. whose book, "The Glass Grant of Palomar," on the 200", is reviewed elsewhere in the present number and who lives in Ogunquit, Maine, is now lecturetouring here and there among clubs of amateurs, using a heavy assortment of lantern slides. He has also lectured before Rotary Clubs and even Women's Clubs, but here he tempers his technicalities to the shorn lambs.

WHO can excel the record of C. P. W Dayton, Lyford, Tex., for telescope pier? His is 2200' deep! Because his locality is underlain by a 40' stratum of quick-and, trains moving within five miles of the telescope caused serious shiminying. An 8' concrete pier made it worse. He felt whipped. Then came an oil company, drilled a 9000' well on his land. Dry hole. But it wasn't a total loss, for Dayton found that, when he set his telescope on the 2200' of 10%" casing the drillers had left cemented in the bowels of the earth, the telescope had the stability of Palomar. Seismoscope becomes telescope.

TRADE MARKS AND UNFAIR COMPETITION

By ORSON D. MUNN

A TRADE MARK is an intangible asset of a business, yet its actual value may grow so large that it becomes the very foundation on which depends the whole structure of the business. Because of this fact, every business man should have available such information on trade marks as will enable him to judge with a fair degree of accuracy the desirability of any mark which he may be considering.

Here, in one handy volume, written in non-legal terms, is a simple yet comprehensive interpretation of the Federal statutes and the body of common law relating to trade marks and unfair competition.

REGAL HIGH-LIGHTS

Patent, Trade Mark, and Related Legal Proceedings That May Have a Direct Effect on Your Business

By ORSON D. MUNN, Litt.B., L.L.B., Sc.D.

New York Bar

CRAWLING BABY

THE representation of a crawling baby, when used as a trade mark, is deceptively similar to a representation of another, even though different, crawling bahy, ac-cording to a recent decision of the Court

of Customs and Patent Appeals.

A prominent manufacturer of habies' rubber pants sought to obtain the registration of a trade mark featuring the picture of a crawling baby and in which a second baby was pictured in stooping position first baby. The registration of the trade mark was opposed by another manufacturer of babies' pants who owned a registration featuring a baby in crawling position. The Court recognized that the two marks were different in detail but held that the dommant feature in each mark was the representation of a crawling bahy and that unless the marks were placed side to side there was a danger of confusion. Under the circumstances the opposition was sus tained and registration of the first mentioned trade mark was refused.

CHINESE-AMERICAN

FEW Americans realize that the United L' States maintains a court in China where certain of the rights of American citizens and of American corporations in China are determined.

One of the recent cases decided by the United States Court for China involved the well-known American trade mark Coca Cola. Suit was brought by the owner of the trade mark Coea Cola against a competing manufacturer selling a somewhat similar product under the name of Eddie-Kola. The Court concluded that the name Eddie-Kola was confusingly similar to the trade mark Coca Cols and granted an injunction restraining further use of the name.

In the Court's opinion it also appeared that the name Coca Cola was registered as a trade mark in China in Chinese characters and the Court pointed out that the defendant had voluntarily agreed to discontinue the use of the registered Chinese

SIPHON CAPSULE

THE configuration of an article is not proper subject matter for the registration of a trade mark, where the configuration serves a useful purpose. This is illustrated by a decision of the Court of Customs and Patent Appeals involving a capsule containing compressed carbon dioxide to be used for carffonating water in rechards the soft alphons. The capsule consisted

of a tubular bulb having a peripheral groove on one side of the central portion. The manufacturer of the capsule contended that the groove constituted a trade mark and he attempted to register it in the United States Patent Office. The Commissioner of Patents denied the registration on the grounds that the groove served a useful purpose and the decision of the Commissioner was affirmed hy the Court.

In reaching its decision the Court referred of this character, in which it stated the groove served to hold the capsule in proper position in the holder provided on the soda Under the circumstances the court stated.

"We are unable to escape the conclusion that the groove as an entity possessed utility and, for that reason, under the authorities, is not a proper subject for registration as a trade mark."

CLEOPATRA

THE personal habits of the famous Egyptian queen, Cleopatra, were discussed in a recent suit for patent infringement. The suit was filed by the owner of a patent for a cleansing cream containing milk and it was charged that the defendant had infringed the patent by making similar eleansing cream. One of the defenses raised was that milk served no useful purpose in the cleansing cream and that in order to be patentable an invention must be useful rather than frivolous. In answer to this defense the patentee contended that milk ap-plied to the skin tended to whiten it and referred to the legend of Cleopatra taking daily milk haths claiming that this made her "the only white woman in a darkskinned race

The Court, however, rejected the legend as a myth, held that milk did not have a whitening effect on the skin, and declared the patent invalid. In this connection the

court stated: "But it is well known that milk does not have a whitening effect; that the story of Cleopatra and her milk baths is a pure myth."

MEIN KAMPF

THE well-known book, "Mein Kampf." hy Adolf Hitler, is at present involved in a legal struggle in the Federal Courts. The publisher of an authorized edition of the book owned the United States copyrights thereon and brought suit against the publisher of an unauthorized edition. Pending the final determination of the suit the Court was asked to grant a preliminary injunction restraining any further distribution of the

orized version. The injunction was opposed by the publisher of the unauthorthat the copyright was obtained Adolf Hitler was not a citizen of any country but, on the contrary, was stateless and on the further grounds that Adolf Hitler had not formally signed his copyright.

The trial court denied the injunction but appeal was taken to the Circuit Court of Appeals which held that the United Copyright Law broadly extended the right of copyright to both aliens and citi-zens and that no restrictions were placed upon a person who was stateless. The only restriction or limitation was placed upon an alien who was a citizen of another country. Under those circumstances it is necessary that the alien author either he domiciled in the United States or that he be the citizen of a country which extends re-

ciprocal privileges to American citizens.

With regard to the title to the copyright the Court of Appeals held that Adolf Hitler had delivered the manuscript to the publisher's predecessor in title and that the delivery of a manuscript under such eireumstances constituted a transfer of the legal title to the manuscript. The injunction was accordingly granted pending the outcome of the trial

CO-PENDING

HAT is the effect of an earlier patent, which discloses but does not claim an invention, upon a later patent granted to the same patentee which does claim the invention? This question arose in a recent suit involving a patent for a method of forming rubber tires. It was contended by the defendant that the patent in suit was invalid because the same invention was disclosed in an earlier patent granted to the same patentee. The Court rejected this contention, however, pointing out that the applications for the two patents were co-pending in the Patent Office and accordingly the earlier patent did not form part of the prior art and did not affect the validity of the natent in suit.

CONTEMPT

ORDINARILY, a person violating an injunction restraining the infringement of a patent cannot be placed in jail but is merely subject to a fine which is intended to indemnify the patentee. This is illustrated by a recent suit involving a patent for a frozen confection. On consent of the defendant an injunction had been entered restraining the defendant from infringing the patent. Thereafter, the owner of the patent contended that the defendant had violated the injunction by continuing to sell infringing articles and instituted proceedings to have the defendant adjudged in contempt of court.

The trial court found that the defendant had violated the injunction, adjudged he was guilty of contempt of court, and com mitted him to jail. An appeal was taken to the Court of Appeals and the decision of the trial court was reversed. The Court of Appeals pointed out that the contempt lings were prosecuted by the attorney for the patentee and accordingly were proceedings for civil contempt as distin-guished from criminal contempt. In civil contempt proceedings the court held that a party could not be committed to jail.

RESUILDING a river through a congessed business and industrial district, as was done with the Los Angeles River (see page 254), nocesitates a wide variety of engineering ingenuity. Our cover illustration shows a cantilever type of wall section, to be poured in place. Walls of this type were used in the Los Angeles River project where the right-drawny was narrow and the channel had to make a wartical section to a trapercial section to a

50 Years Ago in . . .

(Condensed From Issues of November, 1889)

CANAL—"The Nicaragua Canal Company, after exhaustive preimmary surveys, horngs, etc., and the preparation of complete maps and profiles, has now started in on actual work. The total length of the route, as finally located, vs 170 unless, of this length, 121 unless is free navigation of Lake Nicaragua and they say long key, experiment only a little developing and improvement; 22 inities of the company of the company of the company of the company leaving 23 unless only of canal excavation. There will be five locks, two on the eastern, three on the western division.

MILITARY BICYCLES—"The art of war is now borrowing from applied science all the resources that are at the latter's disposal, and there is nothing up to velocipedism that is not contributing to the service of the army ... The illustration shows a phase in the use of the military bevele as practiced in England, the illustration of

which we borrow from the Illustrated London Neux. A small body of cyclust, ten in number (two sections and a half-section), with officers and bugler, marching in usual order of half-sections—that is, by 'twos—are attacked by cavalry. At the word of command, 'llait!' Prepare for cavalry!' Form square!' each man dismounts; and the respective second ball-section meve up alongside their first half-section, so as to form a line of four men in front and cart, with a half-section of two men between them. —The rifles are liked out of their clips as the machine are . . . placed upside machine, sets his whole popularies road with a touch of his finger. Such a fence, apart from the cheuser de fives of baycout behind it, forms an obstacle which few bores, if any, would face: and the men inside, in perfect security, can pick off the advancing horsemen with deadly effect."

AUSTRIAN 'PHONE-"Long-distance telephonic communication was opened on October 1 in Austria between Vienna and Prague, a distance of 220 miles. Every subscriber in Vienna can now communicate with Prague, and every word can he perfectly understood and the voice recognized."

EFFICIENCY—"After a steer goes into a slaughter house nowadays, the only thing that is wasted is his dying breath, and if it were possible to find some use for that, no doubt it would be caught and preserved. Nothing else is wasted, from the tip of the tongue to the brush on the end of the tail."

BRIDGE.—"The Illinois Central opened in \$2,50,000 bridge across the Ohn River at Cairo on the 29th ult. . . . The bridge proper is 2 miles long, and the approaches 4 miles long. The bridge is 38 feet above high water, and 110 feet above low water. The piers are in pocumatic caisons, and are auties 50 feet below the bed of the treer. . At this depth below the river bed no foundation was reached, and ty ass impossible to shir the prest further. They were consequently packed with sand, and the immense bridge is really sustained by the friction of the sand on the sides of the piers."

ARMOR PIERCING—"At the Paris exhibition the firm of Holtzer show a shell which pierced a steel plate 10 inches thick and landed entire without a flaw 800 yards, or nearly half a mile, distant from the target. Only the point of the shell was slightly distorted."

AFRIAL PHOTOGRAPHY..."A new use has been found for the carrier pigeon in Russia...carrying negatives taken in a balloon to the photographer's dark room."

IRRIGATION —"A large force of men is at work constructing an irrigation canal fourteen miles long, to irrigate a tract of 50,000 acres in Fream County, California. The canal will be 60 feet wide and 6 feet deep. This tract of land will be cut up into 20 acre farms and placed on the market."

ARCENTINA—"The Argentize Republic is growing at a really remarkable rate, Burnes Ayres, its capital, having a population of nearly half a million. In 1888 it had foreign commerce of 2200,650,000, of which \$112,41,000 represented imports, including \$44,000,000 coin, and \$106,280,000 exports. Its demands for supplies for the construction of railroads, which, in 1887, were only \$3,500,000, rose in 1888 to \$13,500,000. Of agricultural products, its exported in 1887 212,572,200, against only \$8,431,356 the previous

WELDING—"The Thomson Electric Welding Company, at their Lyna works, have . . . been able to weld wire cable 15/16 inches in dameter for a cable to be used on a cable ralitread, aboving greater efficiency than was thought possible in doing this very difficult work. Although the strength of joints obtained by spikleng was about thirty percent that of the original cable, yet it was found from tests made at the Watertown areasal of electric welds made of this cable that eighty-seven percent of the efficiency of the rope inself had been obtained in these welds."

JAPAN—"Let us take a glance in the direction of Japan. Here we are assumished by the wonderful progress she has made since Perry's expedition, and especially during the last twenty years. Here power and prosperity are steadily increasing. The recent adoption by Japan of a constitutional form of government was a great advance in the path of progress, and marks a turning point in her history. Japan is destined to be one of the great states of the future."

PULLMAN—"The . . Pullman's Palace Car Company . . . is now supplying with sleepers 117,854 miles of the 160,000 miles of railroad in the United States . . . The total number of employes of the company is 11,063, and these employes received in wages nearly \$6,000,000 during the past year."

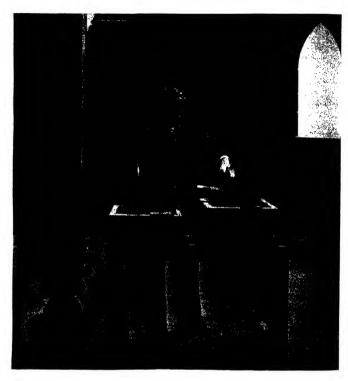

AND NOW FOR THE FUTURE

LIGHTNING IS TRAPPED AND DISSECTED

SGIENTISTS have almost literally snatched bolts of lightning from the skies with the device pictured above. Installed atop the 24-story Cathedral of Learning in Pittsburgh, by Westinghouse engineers, it is called a fulchronograph because it measures both time and amperage of a lightning stroke, broken into tury buts for analysis. Already it has captured one bolt lasting 1/60 of a second and having a maximum current of 21,000 amperes. Its heart is a slotted wheel—filled with projecting laminated magnet steel films—which is rotated through two coils which earry the total surge of lightning that passes safely through a new type of arrester Because of the speed of the wheel and the number of fins, the device can make a recording every 40 millionths of a second. It will give valuable assistance to engineers perfecting power line protectine equipment.

No sincerce is a motor expedition through the Sahara. Though the great desert (Sahara means "desert") is very largely rock and not the traditional sand, enough of it really is sand to provide a motorist's nightmare. Note steel channels under wheels

A Lost World Refound

The several hundred thousand years man of the lover and modile Paleslikith Age roamed over the tercovered expanses of what a now the Sabara, trapping game and chipping stone implements of fixed, almost unchangeable, design. Then the rainfall dwindled, probably because of the final recession of the ice-cap over northern Europe. The people were forced to accommodate themselves to the changed conditions.

We know nothing of the details of human movements during this enormous period, and very little even of the out line. At some unknown date, many thousands of years ago, the people of the North African plains began to domesticate cattle and to pasture herds in the thinning vegetation. Later on they learned to eat cereals as well as meat, and ground some sort of wild grain. These changes appear to be connected in some way with the development of the Noslithio culture with its bewildering variety of stone implement types.

Then, very recently, between 5000 and 10,000 years E.c., there came a further stage of desiccation. The great plains stage of desiccation. The great plains dired up and were abandoned. Man migrated to the highlands bordering the desert where more rain still fell, and to the banks of the river Nile where they could grow gain without the need of any zain at all. Here began that settled life which, attunized by contacts with

On a High Plateau Far in the Sahara's Isolation, Archeologists Have Discovered Evidence of Early Man's Culture... A Land Formerly Wet and Fertile

By MAJOR R. A. BAGNOLD

A sketch-map showing the route of the expedition from the Nile 500 miles to the west into deserts so uninhabited that the trip seemed like a visit to a strange planet

more advanced communities in the east and northeast, very soon gave birth to the great civilization of ancient Egypt. Archeologists have concentrated largely on this last settled phase, but no funds have been available for a systematic examination of the old mother-lands, chiefly because the Libyan Desert is so vast and waterless that, until recently, prolonged and detailed work far away in the interior was thought impossible.

This great desert, roughly the size and shape of India, is indeed overwhelming in its lifeless silence and its sandy desolation. No vegetation of any sort exists except in the ones, for even a sprinkling of rain now falls on any one place less often than once in ten years. Seeds carried by the wind may germinate after a rare shower, but they quickly die in a ground whence all the fertile humus has long ago been blown away. The oases lie at the bottoms of deep and wide depressions, often surrounded by cliffs. They have been sexuaded by cliffs. They have been sex-

cavated by the vind down to the level of the underlying artesian water which originates in rainfall far away on lands outside the desert region. The osage mearest to the Nile and to the Mediterranean are large, and support a permanent population, but the majority consist merely of a few date palms, some swamp grass and reeds, all struggling to live in salt-encrusted soil. Some are mere water-holes which become filled with sand and have to be dug out a fresh by travelers needing water.

But even the water-holes are from 200 to 400 miles apart. Between them stretch bare rock plateaus, dead-flat sheets of sand a single one of which may be 5000 square miles in area, and ranges of giant sand dunes running straight and continuous for hundreds of miles. One or two ancient and now disused caravan routes cross the corners of the desert from one oasis to the next, but it is unlikely that any Bedouin tribes have roamed over such a landscape since the final drought overtook it thousands of years ago. For, without grazing on the way, no camel can do a tourney of more than 350 miles, or 15 days, without water; and half such a journey is an

AN expedition by car into the interior resembles a voyage of discovery at sea. With three specially equipped light vehicles a party of six can be self-contained as regards motor fuel for 1400 miles, and can remain for long periods out of reach of water. Though tire marks persist in some places for 25 years and longer, there are no regular beaten tracks; and for fear of losing their way travelers prefer to steer their own route. keeping a dead-reckoning course by day, and checking their position by the stars when camped for the night. Water is sealed in four-gallon cans, and may be kept in depots for many years without ill effects. One quickly becomes accustomed to a daily water ration of only

four pints. Kit and equipment are cut to the hare minimum to save weight for essential supplies. No tents are carried; one sleeps well on the open sand, without fear of attack by man or beast, by insect or microbe. The air is keen and envigorating in winter. Yet great caution and forethought are necessary. A party stranded beyond walking distance of an occupied oasis can have no hope of surveys?

Within the last 15 years many such expeditions, led at first by the great Egyptian explorer Prince Kemal el Din. and later by the writer and others, have penetrated westward from the Nile beyond the frontiers of Egypt, even as far as the Thibesti Mountains 900 miles across the desert. The object, being largely geographical, great distances-4000 to 7000 miles-were covered rapidly on each occasion. As a result, the curtain of mystery and legend that had hung over the country since ancient times has been lifted All the major geographical features, including the existing oases and the low-lying areas where water might be found near the surface, have now been mapped, albeit rather hastily. Some idea, too, of the immense wealth of archeological material had been gained

In 1938 a new experiment was tried out successfully. A party of nine men,

Cave paintings in red, white, yellow. Age unknown--probably between 4000 and 6000 years, yet unused pigments lay on the ground below, just as the artist had once left them

Below: Top of the Gilf plateau, showing some of the cliffs, 1000 feet in height, which surround this odd, remote world set stop of another odd remote world in the desert's fasiness

including the Egyptologist O. H. Myres and three native diggers, was enabled, through the generosity of the late Sir Robert Mond, to spend two months in a detailed examination of one promising area lying 160 miles from the nearest well.

In the very center of the desert, and at the extreme south-west corner of Egypt, lies the solitary mountain of Uweinat. Northeast of it, just visible on the horizon, the level of the yellow, featureless plain rises abruptly by a continuous 1000-foot wall of cliffs, for all the world like some black forbidding coastline, to the isolated plateau of the Giff Kebir.

The general outline of the plateau had already been mapped roughly from below, and its cliffs had been traced 150 miles northward till they disappeared under the mighty billows of the Sand Sea dunes, but neither the deep winding creeks and fiords which were seen to penetrate the outer wall, nor the upper surface beyond the flat monotonous skyline of the cliffs, had ever been explored. Though now completely waterless, it seemed most probable that the extra rainfall induced by these highlands would have continued to support a remnant of the old population long after the plains below were dead. If so, much interesting archeological material

was likely to be found. Our hopes were justified to an almost embarrassing ex-

tent. The expedition was indeed a journey into the past. For in this country time stands still. Nothing changes; nothing has been disturbed. The Neolithic grinder yet hes in the hollow of the stone quern, just as some Stone-Age woman left it ages ago. The very hearths are there, strewn about with beads, trinkets, and household tools. The ashes look no older than those of a modern Bedouin encampment. On the walls of caves under the great cliffs there still survive the vivid paintings of the ancient people themselves. One sees folk clad in strange primitive garments engaged in lively dances, and tending cattle that would now find no single blade of grass. In the same caves, and on the rocks

nearby are older paintings and cruder incised drawings of far earlier peoples shown hunting beasts that have long since disappeared.

This timelessness constitutes a difficulty, for one never knows into what age one has by chance arrived. Our first camp beneath the cliffs, sited among remains of a Neolithiic folk whose date was guessed as about 5000 n.c., was found to border also on the dim past of 200,000 years ago; for it lay on the edge of a much larger settlement of Acheulean man whose distinctive and well-known Paleolithic implements covered an area of more than a square mile of country and mingled with those of the later age.

For the first three weeks, while the archeologists were at work on these sites, two of us with a single car threaded our way along the bottoms of each, in turn,

A dry valley penetrating into the Gilf plateau. A car, seen as a dot behind two rocks jutting out of the sand within the circle, gives the scale of grandeur

Left: On top of the Gilf plateau today are tracks made thousands of years ago. In all this time there has been nothing to change them: an almost wholly static world

of the long gorges that pierce the Gilf plateau, mapping as we went. Always the same towering cliffs hemmed us in. Counting all the branches and ramifications of the valleys, the total cliff frontage must exceed 2000 miles, yet nowhere apparently could a route be found by which a car could be driven to the top; and we despaired of ever being able to survey the "Lost World" above. At last, however, a very tall sand drift was discovered whose upper slope spanned the final hundred feet of overhanging rock. After four abortive attempts to charge up it with our car unloaded, the skyline suddenly fell away: we were upon a rock surface even flatter than the plains below.

To our astonishment a row of cairns already marked the spot, and well-beaten tracks led away into the mirage over the unknown table land. We had unwittingly hit upon a pass probably last used by the Stone Age people when the lifeless yellow plain below was green.

D URING the days spent on its top the cill forced upon us the complete illusion of living upon a cliff-girt island rising from mid-cosan: the endless succession of headlands, all of even height, the cliffs beneath them falling shear from the flatness of the landscape without preliminary drainage alopes, the

limitless plains 1000 feet below, so far down that their blurred yellow features fade away into the shimmering haze. Even more striking was the steady booming of the wind that sweeps continually over the plateau and swirls away into space over the edge of the cliffs: nothing could better imitate the roar of breakers on a distant beach.

There grew also an uncanny fancy that the ancient people were still about —that there was nothing between them and us. The place has the utter remoteness of another world. One felt suspended high above the desert below, itself many hundreds of miles from the nearest habitation. The surface is a harsh barrenness of broken rock. Yet a network of paths cross and re-cross it. Lines of stones are laid out in curious patterns, as if by children playing at forts. Implements and stone flakes are everywhere; near the cliff edges the ground is literally covered with them, some blackened by the sun, but others so fresh they might be yesterday's chippings. We expected at any moment to witness the return of their makers, uncouth figures clambering up the skyline of the cliffs, hammer-stone in hand. to resume their eternal rock-breaking.

Life during those two months was by no means uneventful in other respects. Violent sandstorms broke upon our little camp, which was once nearly buried, in our absence, by the shifting of a nearby dune. On three occasions we heard the famous "song of the sands," each time in the stillness of the night. Without warning the whole ground reverberated for many minutes with a loud and low-pitched hooting that issued from the surrounding dunes. Operating 200 miles away from the rest of the party two of us became stranded owing to a serious accident to our one car. and had to walk 25 miles to a pre-arranged rendezvous with the others, carrying all our supplies of water and food on our backs. But, to the writer at least, the most lasting memory of the expedition doubtless will be a trivial incident which happened in a cave in which we had taken shelter for the night from the cold wind. The beam of a torch fell on an artificial rock ledge. On the ledge lay a solitary stone knife left behind by the last occupant untold centuries ago, just as we ourselves would em: 'our pockets before going to bed.

[The "booming of the wind," described by the author, is due to myriads of acolian whispers—alight sounds in the vortexes in the lee of minor obstructions but the "song of the sands," also mentioned, is not clearly understood by

scientists.—Ed.] This expedition has proved the possibility of archeological work under the worst desert conditions. Years of patient work will be required before the complex story of man's wanderings in North Africa can be disentangled. It is to be hoped, however, that the evidence so marvelously preserved can be collected while it is still intact, before the adventurous sight-seer has unthinkingly rifled the sites of their most important implements, and before the artist, intent on copying the precious wall paintings in the caves, has trampled on the contemporary floor relics which alone can correlate the paintings with the implement sites outside.

RIVER REBUILT TO CURB FLOODS

os Angeles River during the flood of March 1938. Abrupt curves, where river breached and caused damage, have been straightened

NDER conditions existing until recently, according to Major Theodore Wyman, Jr., U. S. Engineer Department district engineer, a great flood would practically cut off access to the city of Los Angeles, with its population of 1,500,000. In fact, Major Wyman

pointed out that the wide plain on which Los Angeles is situated is under a more dangerous flood menace than any similar region in the United States.

Accordingly, Army engineers and the Los Angeles County Flood Control District are literally rebuilding the Los Angeles River, a stream which, in 40 miles, experiences a fall equal to that of the Mississippi River between Omaha, Nebraska, and the Gulf of Mexico. Rebuilding the river is part of a broader flood control

plan. Already Los Angeles County has spent \$60,000,000 in building parts of the protective works. Present plans call for an expenditure of \$70,000,000 more. But amounts of money to be spent give no idea of the engineering difficulties and problems involved; not only must flood waters and debris of the discharging flood be curbed, but also as much water as possible must be conserved to replenish ground water storage. The life of much of southern California depends upon such stored waters

Work to date, recommended by the Board of Engineers for Rivers and Harbors and approved by the Chief of Engineers, has been done at points where floor danger was most imminent. In foothill areas, some 600 basins and Engineers are Protecting Los Angeles and Surrounding Area . . . Flood Control and Water Conservation Dual Aim

By ANDREW R. BOONE

dams have been constructed to trap water-borne debris and to check water traveling at high velocities; channels trol the water flowing from hills and on the coastal plain, enlarged, straightened, and provided with bank protection, or enclosed within reinforced con-

crete channels. The major drainage system of this area is formed by two main channelsthe Los Angeles and San Gabriel Rivers. These are interconnected by the Rio Hondo, through which water from the

have been constructed to conthese basins Below the footvarious channels have been

upper San Gabriel flows into the Los Angeles River. In general, these rivers have their headwaters in the San Gabriel Mountains, a portion of the Sierra Madro range.

Most important of the streams, insofar as their rampages may affect concentrated population, is the Los Angeles River. This stream, 70 miles in length, may be bone dry in summer, and then carry water at the rate of 90,000 cubic feet a second through downtown Los Angeles during a winter flood. Hence, to save congested areas within the city proper, as well as outlying areas, the improvements proposed for the river include construction of a leveed channel from its headwaters to the ocean; construction of three flood-control basins: and channel improvement in two washes which empty into the river, as well as on other tributaries.

Most dramatic, perhaps, are the straightening, widening, and deepening of the river within the congested district

Left: Placing steel for buttresse

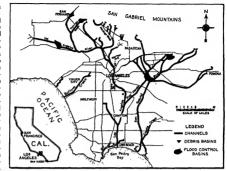

used where vertical channel walls merge gradually into sloping walls

Below: Construction in a congested

area, with mountain on one side and railroad yards on the other. The channel bottom is being paved here

of Los Angeles. Were you to follow the river from its headwaters (see map) you would first come upon an excavated trapezoidal earth channel for a distance of some eight miles; a gunite trapezoidal channel for 5.3 miles above the junction with Tujunga Wash: a concrete and rock paved channel from this wash 7.6 miles to the junction with Verdugo Wash; and a trapezoidal channel with concrete slab or grouted rock bank protection from about this point 6.8 miles to Dayton Avenue, with a special concrete section at the inlet of Verdugo Wash. From Dayton Avenue, the channel traverses the congested business and industrial districts for a distance of five miles. Due to limited rights-of-way available and the proximity of main-line railroads on each side, channel dimensions vary throughout the reach. At some points the channel must be deepened, with consequent faster stream flow. From Soto Street to the sea, several methods of construction apply.

wide with side walls 31 feet high, has been provided. Herc, velocity is figured for 83,700 cubic feet a second at about 14 miles an hour.

From many points of view, re-building this fractious stream presents engineering novelty. It is only part of a larger program, however: that of saving both life and property over a wide area of southern California and conserving water that agriculture and industry may not suffer. How well the engineers have built only time and flood can tell.

Left. Settling basin at junction of Verdugo Wash and Los Angeles River, showing baffles (foreground)

> Below: Baffle walls built across the channel (in right foreground) are to guard against over-scouring

Graceful transations are made from inclined to vertical walls. In some sections rip-rap may be hand-placed and grouted, concrete being poured down a spout from a paving machine or delivered via boom and bucket. Elsewhere, reinforced concrete slabs may be placed over derrick stone. Again, a transition section of reinforced concrete slab buttresses merges a trapezoidal section, which a vertical wall section, the latter perhaps of cantilever type which is poured in place.

During flood, it is anticipated that velocities through the downtown area will vary from 10 to 24 miles an hour, speed depending upon the section. For example, for a distance of 1900 feet, a cotangular concrete obtannel. 177 feet

TERMITES OF THE SEA

TRESTLE crashed, dumping a train into San Francisco Bay. Nearby, a ferry slip mysteriously collapsed. At Provincetown, Massachusetts, a fish pier fell into the Atlantic. A bridge keeper's house, supported on piling driven into a river that feeds Boston Harbor, tumbled into the water. All of these mishaps, and thousands of others like them all over the world, were caused by the tireless burrowings of the Teredo, a marine creature so fragile that it all but defies human handling, yet sturdy and persistent enough to honeycomb the toughest woods-teak, mahogany, eucalyptus.

Few of man's tiny enemies wreak such destruction. In three years, the Teredo did \$5,000,000 worth of damage to Boston Harbor; in a four-year invasion of San Francisco Bay, 225,000,000. It now seems ready to attack the richest, biggest harbor of all—New York.

This swift, secret destroyer has been with us for centuries. The ancient Greeks and Romans called it the ship-worm, and sheathed their flighting vessels with copper against its ravages. Only recently have we discovered exactly what it is, bow it lives, and how its depredations in our harbors can be prevented. The world's battle against it centers in one cheerful, unorthodox man, William F. Clapp, and in the scientific campaign waged by his selfless, happy-go-lucky laboratory in an old barn in Duxbury. Massechusetts.

The true research worker is often marked almost in infanor. By the time was 12, young Clapp had an excellent collection of insects, anakes, and shells. In his freshman year at Harvard, he had no difficulty getting a job as assistant curator of mollusca. Taking only those courses which interested him made getting a degree difficult—he has none to this day—but quickly won him a permanent appointment to the faculty. He taught at both Harvard and Massachusetts institute of Technology, and laid the groundwork for the new science of biological engineering.

FOR 15 years he was chiefly engaged in classifying specimens, makind hose minute examinations which determine whether a given anail or shellfash belongs to a new species or is only a variety of a species already recognized. He might have remained permanently absorbed in this specialized corner of pure science but for a queer piece of wood that was sent to him in 1920.

This specimen of timber came from a

Worm-Like Mollusk... Honeycombs Piling, Timbers... Biologist Studies It In Barn Laboratory... Records Its Depredations... Advises on Protection

By J. D. RATCLIFF

dock in San Francisco, all but eaten away by some marine "termite." What had destroyed it? Those who had sent it wanted to know. After careful study, Clapp named the shipworm of history. Teredo Nayals, as the culprit.

Impressed by his diagnosis and his report, a Committee of the National Research Council, formed to investigate the

A pile from Chelsen, Massachusetts, showing the result of a beavy marineborer attack, especially at mud line

damage done by marine borera along the United States coastline, invited Clapp to join them as a biologist. Confronted by an intriguing practical problem, Clapp maharked on a piece of research which has taken him far beyond his early years of classification and nomenclature in universities and made him a uniquely useful specialist to whom great industrial companies come crying Filologist, silogist, save my dock."

Some people think of research as a peaceful, well-rewarded profession conducted by untroubled men in long white costs working in laboratories supported by great foundations. Nothing could less resemble the conditions under which William F. Clapp has waged his war on

the Teredo. His laboratories have been as makeshift and fugitive as a Kentucky moonshiner's still. One laboratory was a total loss because the harbor over which it was built suddenly was polluted by the seepage from oil tankers Then he set up shop in a 60-year-old schooner, donated by friends, which he fitted up as a marine laboratory, and which the Coast Guard obligingly towed from place to place. When the decrepit schooner sank, be had to begin again Now the general staff, and the intelligence service with its priceless records of the doings of the enemy, Teredo, in all parts of the world, are housed in an old barn. There, in an atmosphere of casual simplicity and hard work, Clapp and his staff of seven young technicians -at \$25 a week-are learning all there is to know about the immense destructiveness of minute animals.

LIFE in the old barn is insecure, hand to mouth, enthusiastically singleminded. Marine borers are discussed with the same vehemence that other people discuss the New Deal-and sometimes that vehemence is all that keeps them warm. One winter the laboratory was so cold that a railroad official found the workers wearing their overcoats. As the railroad company had benefited from their research, it shortly sent a check for \$1000-enough for a new heating system. Equipment is often lacking, but if needed badly enough it somehow appears, and a compound microscope, or a filing cabinet, or a pressure heater for experimenting with wood preservatives, miraculously falls from heaven.

Invaluable specimens and records are stored in this pitifully infammable barn Here is a collection of marine borers larger than those of all the museums of the world put together. Here are individual records of a million individual wooden piles, detailed data on the fluctuating activity of horers in hundreds of harbors. Everything known about the Teredo—as well as fungl, rats, termitesrusts, and other destroyers of structural material—in-croorded here. And a great deal has become known since William F. Clapp entered this atmost unexplored

field just a bit more than 20 years ago. The Teredo, which looks like a greyish-white worm, is actually a molluskar relative of the oyster and the claim. This tribe, together with the crustaces (the family of lobsters, crahs, and shrimp) boasts thousands of species of whose differences would interest only the biologist, but whose one common point is of painful concern to owners of property on salt water: they chew their way mut wooden pilling, leaving no visible entrance on the outside, and tunnel until, very often, it unexpectedly collapses.

A pile which seems quite solid may contain tens of thousands of borers, some as much as six feet long. Bored beams and piles which look virginally sound may be broken over one's

may be broken over one's knee. The Teredo can ruin a costly wharf in as little as two months. It also destroys the planking of boats, and has been known to eat through hawsers, cutting yachts adrift.

Teredos are launched into the world as free-swimning larwe; minute in size but immensely promising. Sea currents will deposit some of them on rocks, some on the mud bottom, and some on wooden pling. Wherever they land, they instantly answer some urge of instinct and start burrowing. Right: Stages in the life of Limneria, a marine borer. A shows a grown female; B, very young specimen (note dark eye); C, Young; D, Immature

Directly below: Still another marine borer, Chelura terebrans, photographed enlarged

Bottom: Teredo Navalis, which sometimes attains a length of six feet. P.P. are the pallets through which food enters and waste is thrown out. S,S are its grinding shells

thick and hard that it cannot be broken by the strongest fingers.

One burrow may approach those belonging to other creatures of its kind, but they never merge. Perhaps only a lime-coated membrane of wood will separate tunnels but each will maintain its discreet identity. The Teredo may bore directly through a timber but it will never bore through to the open on the side opposite its entrance.

When the constant rocking motion of its head has worn out one set of den-

ticles—or teeth—Teredo sprouts another. As many as a hundred rows of these microscopic teeth have been found in one of these creatures. Delicate as they are, no structural wood has yet been found dense enough to resist their borma action. Some varieties of Teredo can even cut their way through poorly mixed concrete.

WHETHER the sawdust Teredo consumes a tile a food is a matter
of dispute. Multipute of agree. He maintains that Teredo on agree. He maintains that Teredo on agree. He maintains that Teredo on the tile of the sawdeenture in home building, and that he
subsists on plankton, the properties of
divident of the seas. Temperopic
of water determines the span of each
of water determines the span of each
works the year round. An untreated
tumber which would last 30 years in Labardor may last only one year in Panama.

Why will these borers suddenly invade a harbor which has been unmolested for decades? The answer usually lies in changed conditions. A three year drought explained the infeation at San Francisco. With very little fresh water going into the Bay, salinity rose and the borers went to work to do staggering damage. Particular attention is now being centered by Clapp on New York

Those that land on mud and rock quickly perish. Those that alight on timber are more fortunate. After two hours of furious work their minute heads, shaped like clam shells, have rasped away a shelter deep enough to enclose the entire body.

As it progresses from the embryonic to the adult stage, the Teredo becomes a rather complex and impressive creature. It sheds the fragile shell with which it does its boring and grows another which is more sturdy.

The Terede maintains contact with the outside world, which is to say the sea, by two hair-like branches of a forked tail. Through one it sucks in saw water and food in the form of minute sea lik and through the other chantes its body wastes. The opening through which those two siphone sextend is no larger than a pinhead, but this portal—a superbly constructed valve—will serve Toredo even though its body attains a learnt of six form.

length of six teet.

Teredo is a master architect, and a superb housekeeper. It removes all debris by the only means at its disposal: by eating it. It lines its tunnel neatly with lime. In some cases this tunnel is so

Honeycombing of a pile by marine borers in only two years, despite the cold waters of Newfoundland

Harbor. In the past, pollution of this port has been so great that borers could not survive. When the present clean-up program is completed, they will almost surely arrive in large numbers and go to work. Such a thing happened elsewhere, notably at Lynn, Massachusetts.

Keeping track of borer activity in a hundred harbors scattered throughout the western hemisphere is the monumental task the Clapp Laboratory has set for itself. Are borers on the increase in Puerto Rico? And what varieties are at work in New Brunswick? Are they harmless ones which work in water too deep to damage piling, or the destructive Limnoria? To answer such questions Clapp's endlessly active mind has devised many ingenious aids. One of them is a test block which gives a continuous record of borer activity; another is a trap which captures specimens for identification.

THE test block is engaging in its aimplicity. It consists of nine small
blocks of pine—ideal Teredo fodder—
bolted to a strap of iron. Each month a
block is removed, and a new one is bolted
in its place. Biologists examine the
block in the laboratory and compare it
with those removed from the same spot
at earlier dates. They can thus determine whether borer population is rising
or failure.

The Teredo traps consist of 30 shingles bolted together. Since the borers refuse to cross a crack, they confine activity to a single shingle. When the bundle is unbolted, whole specimens may be removed examined, and identified.

Test boards are kept at over 400 stations, and traps at scores of others. Maintenance of a board costs about \$5 a month and a few companies pay for this service, but the great burden of expense falls on the laboratory. Test boards occasionally reveal a tremendous upsurge of borer population. In severe cases, as many as 100 Teredos have been found boring within a single cubic inch of wood. Such cases demand instant attention. Several times Clapp has found it expedient to telegraph dock owners quickly to remove all valuable goods from their property because their docks were in danger of collapse.

Once test boards indicate that bores are at work on the piling which supports a large dock, a diver gove down to make an examination. Some of the divers who work for Clapp are so learned that they even know the Latin names of the commonest bores. With astonishing accuracy they can estimate the amount of damage and from this the structural strength of supporting material left under the dock can be calculated.

Corrective measures are determined by local conditions. Where damage is severe, piling must be replaced. Some times concrete corsets are poured around partially damaged piling. Sometimes

The exterior of a badly bored pile gives an appearance of solidity

they are covered with metal sheathing. Damage to the vast, 825,000,000 Army Base in Boston was so severe that Clapp recommended that bulkheads be built which would completely enclose the substructure of the dock, and that fill be then pumped m. This fill prevented further activity of the borers, some ready access to salt water is necessary for their existence.

If timbers in new construction are pressure-tracted with good quality crossote they get complete protection. But in some cases the quality of crossote in so low and method of application so had that even this treatment a valuelesas. The Clapp Laboratory tests the protective power of these materials. Through ignorance or false economy, hundreds of thousands of untreated piles are still being used in United States harbors. As a result, docks last only a third as long as

they should and must be replaced often.

Still, one good word can be said for marine borers: without them the world would have no open harbors. Long ago harbors would have been clogged with rotting driftwood if the borers didn't destroy this debris.

to the beauties of the state of

"TRIENDS are always attempting to T make me change my ways," says this genial biologist. "They want me to keep books and send bills and do things like that. But I'm damned if I will. I am a biologist, not a bookkeeper."

If a check arrives and Clapp feels that he has not carned the sum sent, he returns it. Officials of a large sugar company called for advice about a new dock A telephone call saved them thousands of dollars and they sent a \$500 check in appreciation. Clapp returned it. Not reminite telephone call, he contended, could be worth that much. Another time he refused an annual retainer of \$15,000 from a company which made a wood unservative.

The pleasant, blue-eyed biologist has done practically everything to the Teredo-except eat one. He hopes to get around to this some day. Meanwhile he goalong adding up new facts whose application will save millions of dollars. The aboratory had a zazable deficit last year. It took in \$11,000 and spent \$13.000. But Clapp is not deeply concerned. "If your work is good enough," he feels, "weeple cannot afford to let you fail."

OUR POINT OF VIEW

Battle is Joined

HOW long World War II may last is anybody's guess. How difficult it is going to be for the United States is a different matter. Though not involved, we shall, nevertheless, be faced with a problem of defense against forces that are insidiously subtle. It is not our war, vet our fight to stay out of it will call into play all our forbearance, all our common sense, all the skill of our government.

As this is being written, the war in Europe is but a few days old. Radio and the newspapers have, however, given us already a vast amount of propaganda and counter-propaganda. One side of this war behind the war will have little effect on the individual for he will have formed his opinion prior to the outbreak of hostilities, but the propagands from one's chosen side will tend to strengthen his belief in the righteousness of one cause. Inflammatory rumors will have their influence. Logic may be forgotten and emotion will rule. Hatred may become a neurosis, and the multitude may then clamor for blood, may insist that we enter the fight with men and guns. This we must guard against with all the might of whatever logic and sane thinking are left to us.

The United States is today in a fortunate position in respect to world politics and power. Our foreign commitments relate wholly to the American hemisphere. We have a battle fleet second only to that of Britain, and a large program of ships building and planned. A plan has been launched to train thousands of air pilots each year, and the personnel of our Army and Navy have been in-creased and rendered more efficient. More planes have been ordered to be delivered over a period of years to our military forces. Mechanization of the Army is proceeding with the efficiency that comes of deliberate care. Construction of scores, perhaps hundreds, of new American-type tanks—the best in the world-goes on apace. Slowly all infantrymen are being equipped with the world's finest rifle, the Garand semiautomatic.

The so-called "Stock Pile" Act, passed by Congress last spring, is enabling us to store up necessary vital products against a time of need when imports of them may be cut to a point lower than is at present possible. A War Resources Board has been formed of scientific and industrial leaders. Industry has long since been so organized that, if war should be forced upon us, each plant could quickly and efficiently go on a

war-time footing, "Educational orders" have been given to many of them. Other things, important to us in war, bave been mentioned recently in these pages. For example, there is the new process of molding airplane fuselages, which would increase our plane production enormously. Another is the sizeable supply of manganese from Cuba.

This magazine has long been a proponent of the philosophy of "preparedness for peace" and believes that the above review, sketchy though it be, indicates that particular and important kind of preparedness. Our might is vastly greater than in 1917, our organization so superior that there is no comparison Hence, it is our belief that no nation will wittingly antagonize us, insolently dare us to go in on the opposing side. It is ourselves that we must watch lest we become dupes of silver-tongued agents who would embroil us in troubles out of our own bailiwick. We may give our sympathy-which is of the heart-where we will; but through it all we must keep our heads .- F. D. M

Communication

AT first thought it would seem that the peculiar techniques of radio broadcasting-spot news, high-geared commentators, and so on-would give the whole world a grandstand seat in the event of war. But when the situation grew tense in central Europe, when fateful September 3 rolled around, the humming of the air waves brought thinking people to the realization that a communicating system was more than falling down on a job; it was providing a medium whereby misinformation strode side by side with information, and no sieve was offered through which they could be separated.

The preceding editorial hints at the propaganda possibilities of radio. But there is much more to the story. Operation by belligerents of stations under faked call letters, spurious dispatches, "blanketing" of legitimate stations-all teach us that we will do well to take radio news broadcasts, at least for the duration, with more than the proverbial grain of salt,-A. P. P.

Howling For Knowledge

DOZEN years or so ago it was ascertained by means of polls conducted in the interests of the press that the branch of science which "pulled" hardest with the general newspaperreading public was the one having the least practical usefulness-astronomy.

This startling discovery astonished the newspaper world. Since the press is the reverse of stupid, it gives the public just what is asked for and it therefore greatly increased its regular ration of features and news stems on astronomy. This astronomical emphasis has been going on in the press for a decade or so and now it is bearing a heavy crop of fine fruit. The masses, and no longer merely a limited number of better-thanaverage educated enthusiasts, have now become strongly astronomy conscious.

In Chattanooga a small group of advanced amateur astronomers recently pooled their efforts to make possible a public observatory, whereupon thousands and thousands of people-just average "folks"-visited and continue to visit that observatory. Mountaineers have tramped in from the distant hills to see the stars through a large telescope for the first time in their lives

Not long ago David Dietz of Cleveland, science editor of the United Press, a man who has one foot in astronomy, the other in the newspaper world, decided to make a test of interest in astronomy among the masses and put on a public star party Ten telescopes made by amateur astronomers in Cleveland were rounded up, placed in a public park, and directed at different celestial sights; one at Mars, another at Jupiter, and so on. Previously the event was announced in local papers. Would the party be a failure? Would the people take one look and amble off home? Would they come at all?

More than 5000 people stood in line till after midnight awaiting their turn to see what these objects, about which they had been reading in their papers for years past, look like. Patiently? No. Cleveland had to send two squads of police to keep them in line. Pop venders appeared out of nowhere and did a rushing business. When, at 1:30, the last eager star-gazer left the park, it resembled a battle-field, littered with paper, Crackerjack boxes, bottles.

Only a howling mob? Yes, but not a disorderly one—just eager. Only tabloid readers? Probably largely so. Is that bad? No-all to the good!

These successes give answer to those persons, schooled but essentially ignorant, who still insist on rating everything on a basis of its practical usefulness. It's a mighty good sign when 5000 of the plain people will stand in line and vell "Hurry up" in order to get a better idea of man's place in the universe: for that is suspected of being the real philosophy behind it all .- A. G, I.

Hunting The Mesotron

WHEN confronted with the eremounting clutter of assorted
atomic and authority particles
brought to light by photolists in recent
years, one naturally resolution to continue the reyears, one naturally resolution to continue the resent particle as a might a bug collector hounding down
a specimen, or do the particles merely
fly in through the window one day and appresent themselves? Let us consider,
for example, the latest problem particle
in physics—whe mesotron.

Although there has been considerable controversy as to where it is found in nature, it is now known that the meso-tron occurs only in the cosmic rays. These rays, which rain in upon us constantly from outer space, have been known for many years. Nevertheless, the question as to just what they were was not settled until scentists turned to the Wilson chamber with which they proposed to study their true nature.

The Wilson chamber consists of a shallow glass cylinder covered with a glass plate. The interior contains a small amount of liquid, such as water or alcohol, which evaporates, filling the chamber with vapor. In the bottom is a piston which, when suddenly pulled out by a suitable mechanism, causes the vapor to expand and condense. If the expansion is very carefully adjusted so that condensation just fails to occur, any electrons or other charged particles which traverse the chamber will leave faint tracks of condensed vapor in their wake. By photographing these tracks, much can be found out about the nature of such particles. For example, their velocities can be found if the chamber be put between the poles of a large electromagnet. The effect of a magnetic field upon a moving charged particle is to cause it to be deflected in a direction perpendicular to the magnetic field and to its original path. Thus the track will be bent by the magnet into a circle. The radius of the circle is proportional to the momentum of the particle and, since momentum is the product of mass times velocity, knowing the mass, the velocity can be found.

At first, experimenters merely set up their chambers and expanded them at regular intervals, hoping to eatch cosmicracy tracks by accident Considerable miprovement was made in getting photographs when Geiger counters were used These instruments consist of a thin metal cylinder surrounding a wure and put in side an evacuated tube. High voltage is This Recent Addition to the Fast-Growing Family of Sub-Atomic Particles has Already Created a Place for Itself in Physical Theory and Experiment

By CHARLES W. SHEPPARD

connected between the wire and the cyl inder and adjusted until just helow the point at which a discharge will occur if a cosmic-ray particle shoots through the tube, the discharge is set off and can be made to trip an electrical circuit, expanding the chamber With such an arrangement, it is possible to catch a cosmic-ray track at every expansion

Figure 1: Two cosmic-ray showers, one in the chamber wall and one in the plate, show that particles from showers produce showers. Each particle has an energy of several billion volts. (See the text below.)

In practice, two counters are used, placed one on each side of the chamber and connected in such a way that the chamber expands when the particle goes through both. Thus, the chamber operates only when a track goes right through it.

The study of coame rays with the Wilson chamber was immediately fruitful. When a barrier of lead was put into the chamber, many pictures aboved a strange phenomenon. A coamic-ray particle entered the chamber from above and went on into the lead plate. It merged from the other side and with it, like an explosion, came a regular forest of other particles (Figure 1),

Such occurrences are called showers. Up to this point, the result had been quite straightforward. There was good reason to believe that the tracks which were observed were caused simply by clectrons. In particular, a study of the shower particles showed that those produced by showers could themselves produce showers, and their energy loss in going through the lead plates showed that all were electrons However, the many workers on the cosmic-ray problem frequently observed other particles, and although their tracks looked just like electron tracks, they behaved in a different manner (Figure 2). To understand why the scientists were puzzled by these other particles, we must consider how charged particles lose their energy in traversing matter.

LET us consider first a fairly heavy hydrogen atom, called the proton. Since the distance between the atoms in a plate of lead is about 100,000 times the size of the proton, the latter cannot lose energy by friction in passage through it, as would a bullet in a plece of wood. It is known that almost all the energy loss which a proton suffers is due to the electrical forces that it exerts on the electrons in the material through which it passes. About thirty volts of energy are needed to pull an electron from an alr molecule. The number of these dissociated air molecules, or ions, can be measured and it is found that, in air, a proton of 1,000,000 volts energy creates so many of these ions that it loses almost all its energy in less than half an inch of air. In the case of lead, it will scarcely penetrate at all. Energy loss by ionization, as this type is called, is characteristic of heavy particles which do not move with very high speeds. Although the process is very complicated, it has been found that the energy loss is greater the slower the particle travels, and a measurement of the rate of energy loss gives an approximate idea of the velocity of the particle.

A totally different type of energy loss is also known. Particles such as electrons, which are light but travel at high

speeds, lose their energy by giving out electromagnetic waves when they pass through matter. This is how the rays are produced when the electrons in an X-ray tube strike the target. This type of process is called energy loss by radiation.

From what has just been said one can see that a study of the way in which a charged particle loses energy should give quite a bit of information about it. Such energy-loss measurements were attempted but were hard to make. The energies of cosmic-ray particles run in billions of volts. Such particles move so fast that none but the largest magnets will bend their paths enough to permit measurement. However, careful work gradually yielded the necessary information. As the measurements slowly accumulated, suspicion grew into certainty. Those tracks which produced, or were produced by, showers lost energy in just the way that electrons may be expected to do and were undoubtedly electrons. On the other hand, those tracks which occurred without showers were different. for they had a penetrating power very much greater than any other charged particles beretofore known. Of the many experiments to demonstrate this penetrating power, one of the most spectacular, in which the particles were made to pass through more than seventeen inches of lead, was made by Street, Woodward, and Stevenson, at Harvard University.
In 1937, Dr. Carl Anderson and Dr.

In 1937, Dr. Carl Anderson and Dr. Seth Neddermeyer, of the California Institute of Technology, put forward a tentative explanation in a paper published in The Physical Review. This paper contained a plot of the energy

Figure 2: "Picture" of a mesotron. The particle comes in with high speed, making a very faint track, slows down in the central plate, and emerges going more slowly, as is shown by the heavier track as well as by the sharper curvature.

losses of cosmic-ray particles, showing how the non-shower particles lost much less energy than the shower particles (Figure 3). Let us suppose, they said, that the unknown particles are heavier than electrons but lighter than protocome will travel saster than protons and not lose much energy by soinzation. On the other hand, they would not travel so fast as electrons and would not lose much energy by redistion. This would explain their low energy loss or great penetrating power.

In order to substantiate their theory, it was thus necessary to determine the mass of these partueles. The difficulty lay in the fact that only the momentum can be measured when particles are deflected by a magnet. The mass is known only when the velocity can also be found. Several workers at once attempted to measure the velocities of the unknown particles by the following method:

A charged particle traversing a cloud chamber leaves a track because of the ions it produces in its path. The vapor in the chamber prefers to condense on these ions, and with the right expansion, every ion picks up a tiny droplet of condensed vapor. If the expansion can be delayed a fraction of a second after the particle passes through, the ions will have time to drift apart so that the droplets can be counted with a microscope. If the number of ions in each centimeter of track is counted, the rate of energy loss can be determined and this will give an approximate knowledge of the velocity of the particle. Such measurements are actually a good deal more difficult to make than a description would indicate. Conditions must be just right and not every picture will do. However, in 1937, Street and Stevenson, and, shortly afterward, Anderson and Neddermeyer, obtained the pictures they were looking evidence extending back over several years. Measurements of the mass of the particles from these pictures showed that they were somewhere between one and five hundred times as heavy as ordinary electrons. Several suggestions were made for naming the new particle and Dr. Anderson's suggestion of mesotron received the most support.

SCIENTISTS had scarcely had time to inquire as to what place there was for the mesorron in existing theories when a bolt from the blue came in the form of an already existing paper in the rather maccessible Proceedings of the Physico-Mathematical Society of Japan. In this paper, published almost two years before the discovery of the mesotron, the Japanese physiciat, Yukawa, had announced a theory explaining the force of attraction between the neutron and proton. The theory

stated that these unknown forces holding the atom together could be explained if one assumed that there existed a new particle with the charge of an electron but of larger mass. If, as many scientists believe, the Yukawa particle actually is the mesotron, then not only is an experi-

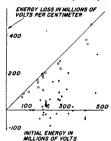

Figure 3. Principal clue to the existence of the mesotron. Diagonal time represents the total loss of energy in one centimeter of platinum plate. The circles clustering close to this line are electrons. Dots clustering near the bottom of the graph are mesotrons

mental discrepancy accounted for but also a vacancy in theory is filled by its discovery.

Needless to say, the appearance of the meetorin upon the scene has stimulated the whole field of cosmic-ray research to new activity. Experimenters are redoubling their attempts to make accurate measurements of cosmic-ray tracks using larger magnets and Wilson chambers than those formerly employed. Thus more precise information will soon the obtained with such appearatus.

Let us now return to the question we made at the beginning. Is particle hunting a sort of glorified insect collecting or does the physicist find the particle one day at lunch in his soup? In the first place, both alternatives place an undue importance on the particle itself. Such a discovery is never merely a new head to hang on the wall of the physical laboratory. Instead, it invariably represents an important contribution to physical theories and thus frequently extends human knowledge in many different directions at once. Let us consider the senior member of the "tron" family, the electron. This particle is a crucial link in almost all the physical theory devel-oped since 1875. It is safe to say that, without our knowledge of the electron, we would have no X rays, no radio. and no long-distance telephone. Perhaps one day, the mesotron will be as indispensable.

COULD WE DEFEND OUR PORTS?

Whether or not important American ports are sufficiently well fortified to stand off a possible invasion remains an open question. Only an actual attack upon one of those ports would provide the answer. The drawing on the opposite page is presented as an example of what might happen but, unfortunately, military strategy is not so sumple as that. With this drawing before us, we still must lean heavily upon past military lessons

and experience. Bombing planes cannot cross the wide oceans that surround us and still deal any effective blows against us. Hence, any invader would have to depend upon only those planes which his carriers could bring. This immediately unlifies any belief which he might have that the airplane has changed naval warfare condutions radically since 1915. In that year, the British fisseo at the Dardanelles proved rather conclusively that it is futile to launch a naval attack upon land fortifications.

We are here concerned not with why an enemy might attack us nor how he would get through our first line of de-fense—the Navy—but rather with the possible reception he would get were he suddenly to appear on our "doorstep." For this purpose, we have shown mything the suddenly to appear on our "doorstep." bunched and hence thrown out of persective for obvious reasons.

As soon as the enemy's fleet nears the city-which might not have much warning-preparations for the defense of the port will get under way according to plans long before worked out. Necessarily, these plans include bringing up more guns and equipment, plane detectors, range finders, searchlights, and many additional men from camps near the city. Firing of anti-aircraft guns would begin long before the fleet itself is in sight. Its planes, based on carriers left perhaps 75 miles out at sea, will attempt to destroy gun emplacements in the city's forts. Doubtless, they would resort to the practice of divebombing, an American trick learned by foreign aviation, oddly enough, from an American moving picture, "Hell Divers," several years ago.

This surprise attack from the air might cause some damage, but the organization of the defense would, nevertheless, proceed rapidly and efficiently. All available units of all our armed forces—Army, Navy, and Air Corps—would be co-ordinated and unified under an appropriate commander.

An Imaginary Attack on a Mythical Port Shows Sort of Action That Would Take Place

He would keep track of, and drrect the movements of, the additional forces coming up from the rear, most of which is motorized and some, as in the case of the 12-inch and the 16-inch guns, or railway mounts. These latter large guns would be run in on the railroad spur shown at the right of our drawing. The 16-inch guns on railway mounts, as well as those of the forts, would be able to match anything the enemy capital ships would have, being able to throw one-ton shells for a distance of about 40,000 yards.

Against the enemy's airplanes would he directed the fire from several types of guns. Most important would be the 3-inch guns which fire about 25 highexplosive shells per minute to a height of 24,000 to 28,000 feet. Until 1938. we had only a few of these rather small guns. In that year we added about 340 of them to our armament, and since have added more. Another anti-aircraft gun which the defending forts would use is the 37-millimeter gun. This mobile arm fires explosive shells weighing approximately a pound and, being loaded with clips of five and ten shells, has almost machine-gun speed of fire. Furthermore, low flying planes would meet deadly streams of metal from 30-caliber and 50-caliber machine guns. The Spanish civil war apparently proved that machine guns, as contrasted to those firing explosive shells, are ineffective against modern. metal-clad planes. In spite of this fact, it is believed that these efficient machine guns, properly controlled and operating in groups, could cause serious damage to planes.

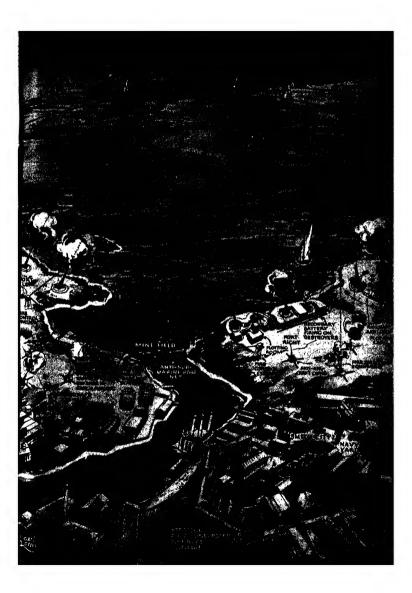

ONCE an enemy plane is detected by the defense, an ingenious range finder, shown in the drawing near the anti-aircraft batteries, would go mto action. This finder is practically automatic. As an observer moves it to keep its widely spaced cross-hairs squarely on the enemy plane, that movement actuates gun-pointing equipment to make the guns follow the plane's movements closely.

As for the fleet itself, wariness would characterize its actions because of the lessons of the Dardanelles. The enemy capital ships would form a line of battle just beyond the range of the largest guns of the forts. The advantage lies with the land guns because of their permanent emplacements which give greater stability and because their firecontrol stations can more accurately plot a moving slip's position. These fire-control stations - shown on the drawing in both Fort Left and Fort Right-form the bases of triangles while their converging lines of sight make the apex of that triangle. The exact position of the ship at the apex is therefore easily calculated, in the plotting room of Fort Right, by the mathematical process of triangulation. Planes spotting shell bursts among the enemy ships. and also "tracking" those ships to predict their movements, would provide further data.

Since the enemy's principal purpose would be to get his capital ships close enough to deliver his 14-inch or 16-inch shells in the forts, he might try to sneak in under cover of a smoke screen. This screen would be laid by squadrons of destrovers which would dash in closely in a sweeping curve, firing their smaller guns furrously. The high speed of these destroyers increases the possibility of their escape but, even if some of them are destroyed by gun fire, their loss is not to be compared with that of a capital ship. It is during their dash close inshore that the secondary guns of the defenders, hitherto useless because of their shorter maximum range, must go into feverish action.

Our drawing has its necessary limitations. We have shown, for example, only one small submarine boat net and a mine field that is actually too limited for practical purposes. These things are more symbolic than actual, for we wished to show only the essentials. In real warfare, far more ships and guns, mines and nets, planes and anti-aircraft guns and detectors would be in such an action. Also there are many other factors, too confidential or too speculative to be mentioned here, that would have a bear ing on the fight. In any case, it is believed that an attack of this sort would result in a stalemate. This does not mean that our ports are invulnerable. They aren't. It is only our ability to draw upon an immense hinterland for enormous support which could save us in such a situation. We do need more large-caliber guns, more and larger antiaircraft guns, and many other important things, but that is another story.

Eclipsing Binaries

It may be questioned whether there is really a "royal road" to the solution of any problem of nature; but some routes do lead us, with less difficulty, deeper into the regions which we desire to explore.

One of the most important of these routes, in our search to understand the stars, is found in the study of the pairs which colipse one another. It has long been realized that from good observations of these systems we can find out things not directly accessible in any other way, such as the real size of the stars, their densities, and the actual brightness of their surfaces.

But even the finer details of the lightcurves, which might almost be called the "embroidery upon the main pattern." are singularly informative.

For example, when the brightness of an eclipsing star (that is, the combined light of the pair, which could not be seen double in a telescope 50 times more powerful than any ever constructed) has been accurately measured and the light plotted against the time, it is found that, between the deep diparising from the successive eclipses of each star by the other, there is a mailler, each star by the other, there is a mailler, ecclipses, the light is hrighter than where the eclipses are just over or just ready to begin.

The explanation of this behavior (which was first noticed in the bright star Beta Lyrae) has been known for almost 50 years. When the component stars are close together, each will be distorted by the tidal forces arising from the attraction of the other. This will make them egg-shaped, with the long ends pointing at one another. As they revolve in their orbits, about their common center of gravity, they will rotate at the same rate, and continue to point toward one another. Half-way between eclipses, where the line joining the stars is at right angles to us, we will see them broadside on. At the middle of eclipse (if the orbit is edgewise toward us) we will see them end on (one behind the other), and just outside eclipse they will be nearly end-on. Half-way between eclipses, therefore, the star-disks will have a greater apparent area than just outside them, and, naturally, we will get more light.

This ellipticity effect has been found in dozens of stars—indeed, in almost all cases when the observations of light are accurate. We might expect to find it bigger when the stars are very close together—and the eclipses consequently A Striking Example of the Extent to Which the Astronomer, Armed with but a Few Observational Data, Can Sometimes Go in Unraveling Puzzles

By HENRY NORRIS RUSSELL, Ph.D.

Ohairman of the Department of Astronomy and Director of the Observatory at Princeton University Research Associate of the Mount

occupy a considerable part of the whole period—than when the eclipses are short and the stars far apart; and this actually happens

The shapes which stars, tidally distorted by their mutual attraction, would assume can be calculated. The theory is fairly simple, in the first approximation (though it becomes intricate when the bodies are very close together). It is found that the shapes depend not only upon the masses, radu, and mutual distance of the stars, but also upon their internal constitution. If the material (supposed to be fluid, so that it yields freely to the tidal forces) is all of the same density, the elongation will be large: but if it is much denser near the center than at the surface the distortion is much smaller. In the extreme case where practically all the mass is concentrated at the center, it is only 40 percent as great as for a homogeneous body.

HERE then appears to be a royal road leading us to knowledge about the inaccessible interior of the stars. As long ago as 1912, Shapley applied this method, finding that the ellipticity of such stars, derived from observation, agreed quite closely with the values calculated by Sir George Darwin for homogeneous massess of fluid.

There was, however, one difficulty. The calculations just described had been made upon the assumption that the disk of each staf (seen sufficiently magnified) would appear uniformly bright all over. Now the only star we can actually observe in this way is the Sun, and it does not look like this, but is only about half as bright at the edge as at an the center. The reason is that the light which reaches us from points near the apparent edge escapes obliquely, and on the average comes from cooler layers nearer the surface.

We might expect some "limb-darkening" of this sort in the stars also. It is not hard to calculate its effects in the case of an ellipsoidal star. If there were two stars of the same size, shape, and average brightness, one presenting a uniformly bright disk and the other darkened so as to be very faint at the limb, it is found that the difference of brightness between the end-on and broadside-on presentations would be 60 percent greater for the "darkened" case than for the "uniform." An observed variation can therefore be produced by a "uniform" star of a certain difference in long and short diameters; by a "completely darkened" one for which this difference is only five eighths as great. and by a whole set of bodies of intermediate shape and intermediate degrees of darkening toward the limb. Unless we can find the degree of darkening in some other way-which is still very difficult-we are left in considerable uncertainty about the real shapes of our stars. and the actual internal distribution of density

But now another royal road seemed to open up. If the stars are elongated as described, their mutual attraction will not be quite the same as if they were spherical. The effects of this have been known for more than two centuries. No perceptible change will be produced on an exactly circular orbit; but, if the orbit is eccentric, the line of apsides (passing through the points nearest the center and farthest from it) will slowly advance, in the direction of the orbital motion. The rate of this advance depends on the radii, masses, and ellipticities of the stars, and also on their internal constitutions, being a maximum if they are homogeneous, and falling to zero when all the mass is concentrated in tiny particles at their centers. This impossible, but theoretically limiting. case is known as the Roche model (from the name of its inventor).

If an eclipsing pair has a circular orbit, the alternate eclipses of each star by the other will come at equal intervals, and last equally long. But if the orbit is eccentric, both the intervals and the durations will usually be unequal. If the line of a paide is a moving, the intervals between the eclipses will slowly change, wringing back and derward be-

tween two limiting values, and repeating these changes after a whole revolution of this line.

For most of the stars which have been observed, the orbit appears to be circular. But in a dozen or more cases uniquelitational between successive minima prove that the orbit is eccentric, and, in allowat all these cases, the intervals are changing, showing that the line of apsides is moving. In two systems a complete revolution of the apsides has been observed.

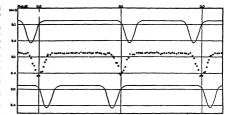

Knowing the rate of this motion, and the sizes and relative masses of the stars, we can calculate the degree of concentration of density toward the center. For the star Y Cygni—the first to be reliably observed—Dugan and the writer found, several years ago, that the concentration must be great

But sgain the once-royal road appeared to be blocked. The theoretical calculation of the attraction of the stars on one another had been made for hodies of the shapes which they would have at their average distance apart; but no allowance had been made for changes in this shape

NOT long afterward Walter went deeper into the mathematical problem, assuming that the two ellipsoidal stars weer rigidly fixed in site and shape, but free to turn on their axes unerveily, and point a little away from each other at times. His analysis led to the remarkable conclusion that, in this case, the line of apsides moved backward while two stars undergo vibrations such that their long ends oscillate to and for about the line joining their centers (usually they oscillate with different rectiods).

Given his assumptions, his conclusions are mathematically sound; but, about a year ago, Cowling pointed out that real stars, being gaseous, would not behave at all like the "frozen," rigid bodies of Walter's theory. As the distorting forces changed, while the stars moved around their orbits, the mobile gaseous masses would tend to take new shapes, corresponding to the new forces; and this adjustment would be so quickly made that it is practically safe to disregard any lag in it, and assume that the shapes of the stars are determined by the forces at the moment, and are most clongated when the two are closest together. Working out the details no simple task-he found that the apsides move forward, but at a little more than twice the rate originally calculated by the writer.

The theoretical problem has now, apparently, been cleared up. When the new equations are applied to the actual data—as has been done in detail for the best-observed stars by Sterne, and approximately, for a larger number, by the writer—it is found that, in every

Light carves of an eclipsing binary with eccentric orbit and rotating line of apsides. Phase in the orbit is measured toward the right. The distance between the two vertical lines labelled 0.0 represents a full period. Vertical distances represent the apparent magnitude of the pair of stars, a measure of their brightness. The dips in the curves are due to the eclipse of one star by the other. The center curve represents the average of all observations. In the upper curve the stars are at periastron (closest togsther) in the latter half of the period, mildway between the two minima which occur closer togsther. The lower curve around, making periastron occur in the earlier half of the period. This variation of the time interval between eclipses is due to the greater speed of orbital motion when the stars are closest together.

However, the above diagram is not immediately related to the particular stars discussed and mentioned in the accompanying article. Rather, it is shown as "a very pretty Illustration," as Professor Russell wrote in suggesting that it be reproduced, "of the changes due to locating spudses in an orbit," and it is taken from an article entitled "The Apsidal Rotation of GL Carinac," by Henrietta Swope and Harried Shapley, in the Bullatin of the Harrord Collage Observatory for July 1, 1932 (No. 999). In the absence of Professor Russell in Europe the above explanation of the diagram was prepared by Prof. D. B. McLaughlin of the University of Michigan. Regular readers of Professor Russell's articles may be interested to know how the illustrations are selected Sometimes he prepares rough tacthers.

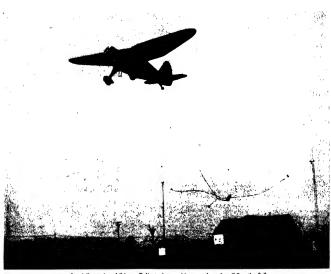

case, the central condensation is high The motion of the apaides is never as great as 6 percent and usually less than 2 percent, of the value which it would have if the stars were homegeneous. It follows, approximately, that the central density of the stars is always at least 20 times as great as the mean density of the whole star, usually more than 50 times as great, and occasionally as much as 300 times.

So far as observations of this type go, the results are consistent—though a lot more observations will be needed to get more accurate data. But an alarming discrepancy now appears between the results of the one method and the other. The two royal reads end in different places—one indicating that the stars are not very far from being of uniform density, and the other that the increase of density at the center is very great.

The answer to this puzzle comes from some theoretical work of Chandrasschhar, who found, six years ago, that a distorted star of this sort should be faintest at the ends, remote from the centerest at the ends, remote from the centerthe surface-brightness being and proportional to the intensity of gravity as this would be observed by an imaginary inhabitant of the surfacehary inhabitant of the surfaceFor such a body the difference in brightness between the end-on and broadade views is much increased—in fact, very nearly doubled. This was first pointed out, five years ago, by the late Dr. Takeda. His results were published (in English) in a Japanese scientific periodical, and escaped notice till the matter had been treated by various other investigators.

When allowance is made for this and for the effects of 'darkening' (which operate almost independently) the discrepancy disappears. The fairly large changes in light which are observed between eclipses arise largely from the difference in brightness between the ends and the middle of the elongated stars—and are increased by the limbdarkening. The real shapes of the stars are not far from those of the Roche model—just as the changes in the orbits indicate.

Much more work remains to be done before this mine of information about the surfaces and the interiors of the stars becomes exhausted. Meanwhile, it is interesting to note that our present fairly satisfactory knowledge has been reached by the work of investigators coming from this country, England, Germany, India, and Japan.

Specially equipped Stinson Reliant plane picking up a bag of mail "on the fly"

AIRMAIL FOR SMALL TOWNS

IRECT airmail service to small cities and towns, previously reserved for large centers of population where the volume of business warrants large airports and mail-handling facilities, is now daily available to 58 localities throughout Pennsylvania. West Virginia, Ohio, and Delaware. Through development work by All American Aviation, of which organization Richard C. du Pont is president, an airmail delivery and pick-up system invented by Dr. Lytle S. Adams has been reduced to practical operation. Flying the air-ways in specially designed and equipped ships, "sky mail clerks" are now able to make deliveries and to pick up mail without the necessity of landing. At the time of writing, the system is in operation with six experienced pilots, some of them of national reputation, and four "sky mail clerks" constituting the flying personnel.

The success of the system, and the

Pick-Up and Delivery Without Landing . . . Made Possible by New System . . . Can Bring Fast Mail Service to the Most Remote Areas

By DR. ALEXANDER. KLEMIN
In Charge, Danift Guggenheim School

regularity with which the service is carried out, indicate its entire feasibility. There is no doubt that it can readily be extended to other sections where its advantages are desired.

While full technical details of the exact operations of this new system have not as yet been released, the accompanying photographs and following description serve to give the fundamentals. The ground equipment necessary consists merely of two steel poles, 30 feet high, set in concrete foundations 60 feet apart.

Each pole is topped by a brilliant orange marker. Stretched between the poles, and attached by spring clips, is a trsns Ter rope from which is suspended the mail bag to be picked up.

mail bag to be picked up.

In the planes used for this service, all standard interior equipment has been removed except the pilot's seat, thus making room for mail bins, pick-up goar, and a seat for the clerk who also is responsible for the operation of the mail-handling apparatus. With this relatively simple setup it is possible to deliver and

pick up mail while flying at a speed of between 90 and 110 miles an hour. Since speed in the essence of airmail service, it is interesting to note here that, flying 1540 miles daily and making 75 pick-ups to serve the 58 communities along the route. All American Aviation's planes are carrying on a regular schedule at a werage speed of 100 miles an hour even under adverse weather conditions. Since the stations are from five to 22 miles apart, such service could not possibly be mantained if it were necessary for the plane to land at and take off from every varion.

Deliveries and pick ups are made in one trip through each station, the operation being as follows: The clerk lowers by hand the bag for delivery, which is inked to the plane by a rope ending in a release mechanism that is under the control of the pilot. He then lowers the grapple hook on one end of a cable that is wound on a shock-absorbing which in the plane. The pick-up cable extends from the bottom of the fuelsage about two feet forward of the delivery one and the two lines are prevented

from fouling by their drag/weight ratios which give them different curves in

When the delivery bag is released by the pilot, before the plane reaches the two poles and transfer rope at the station, it falls clear of the pick-up cable. The plane then passes between the poles at an altitude of 50 to 70 feet above the ground. The pick-up cable then crosses the transfer rope and slides across it until the prongs of the grapple engage the rope and pull at free from the poles. As the grapple pulls on the transfer rope, the mail bag alides along the rope away from the granule. a simple restricting

fitting slowing up the travel of the bag as it approaches the end of the tope where it is checked. It is really this slide fitting, which absorbs much of the slock of contact. that makes possible thutype of pick-up without impossing undue strain on the cable. The remander of the shock is taken up by the absorbing mechanism in the plane. It is stated that

Above: The steel grapple with which airmail pirkens are made. Left: A "sky mail clerk" operating the winch by means of which the bag of mail is recled into the plane. Extreme left: Closeup of the combined winch and shock-has orbing apparatus which is mounted in the plane. The air-oil shock absorber operates when the grapple hooks into the line and prevents undue strain being imparted to the plane listed. Before: The fiber and tracter and the plane of the plane listed. Before: The fiber and tracter and the plane that the contract of the plane listed. Before The fiber and tracter and the plane that the contract of the plane listed. Before The fiber and tracter and helps to absorb transfer energy.

the pick-up is scarcely noticeable to the occupants of the plane. Should the grapple or cable be fouled by an obstacle on the ground, a safety link in the cable will break, preventing any possible accident.

In present operations the pick-up load has been limited to 20 pounds, although loads up to 70 pounds have been successfully picked up in tests.

The mail bags used in this system have been so designed that they will trail smoothly in the air and also that they will withstand the shock of dropping at high speeds. As shown above, they consist of a smoothly rounded fiber nose with a rubber skirt attached and a mail container inside.

Looking toward the rear of the special airmail plane, showing a mail bag ready for delivery and, in background, the mechanical release operated by the pilot

Cancer's Mysterious Puzzle

"PUBLIC interest in the cancer problem is now at the highest point in history," says Dr. James Ewing, one of our foremost cancer experts and director of Memorial Hospital, New York City.

This interest is only natural. We have become aware that cancer is by far the most important public health problem. Some 15,000 die each year in the United States from this perhaps most mysterious of all man's afflictions. Cancer, it is true, is curable—to a certain extent, especially if caught in the early stages—and many are cured, or more accurately, are treated successfully; but the fact remains that many more are not cured.

The great mystery is nowhere near elucidationand on this point all experts agree. Why do some cells subtly begin to multiply aimlessly, to form an unorganized-hence cancerous-growth, which the body cannot control because the growth escapes from the unknown agents that normally keep all the tissues a unified harmony of structure and activities? Such is the problem, simply stated. Yet this simplicity is deceptive, for all man's enormous medical and bioknowledge is at a loss for the answer.

And so, any new clue to a possible answer is fascinating as well as distinctly promising. The discovery of substances which definitely have the power to induce cancer is the most promising of all recent leads—and

surely the most startling "One of the most fruitful lines of cancer research

in recent years has provided the demonstration that cancer may be produced at will m a anjority of the animals treated, with a variety of chemical compounds. For the most part these compounds have been prepared synthetically and their molecular structure is known. They retain their activity undiminished after a high degree of purification. The cancers which may thus be induced experimentally are indistinguishable in their characteristics from the cancers which afflict mankind." So we are told by Dr. J. W. Cook, the English pioneer in the realm of cancer-

Though Science Still is Baffled by the Problem of Cancer's Cause and Cure, Research Continues... Most Alluring Leads of the More Recent Years

By BARCLAY MOON NEWMAN

inducing substances, who, with his coworkers at the Research Institute of the Cancer Hospital, London, has led the world in this line of research.

The story of the discovery of cancercausing chemicals begins at least as far back as 1775. In that year, the London surgeon, Percival Pott, re-

all Mustrations courtesy United States Public Realth Service
Using the fluroscope with X rays in examination of the
chest for cancer. If there is a cancerous growth, a shadow
will be discernible on the screen in front of the, difest

marked on the prevalence of cancer among chimneysweeps and pointed out the probability that soot is the significant factor. Soot, we now know, consults a souther a consult of the consults are t

Later, other occupations besides the sweeping of chimneys were found to be plagued by significantly high rates of cancer. Skin cancer is frequent among workmen employed in the distillation of coal tar. Laborers who apread tar on roads; workers chronically exposed to shale oil and other lubricating oils, makers of certain dyes, particularly ani-line dyes; spinners an continual contact with certain oils—in each of these occu-

pations we observe a suspiciously high cancer rateoccupational cancer.

N 1906. B. Fischer injected a dye known as Scarlet R into rabbit cars. The cells of the skin, after several injections, multiply abnormally, in a manner similar to cancer cells. But when these injections are stopped, cell proliferation ceases-that is, the growths are not malignant and so not truly cancerous. This work has been extended. and one outcome is the use of Scarlet R to hasten the healing of wounds. Another outcome, as we shall see, has led by a tortuous path into the field of true cancer.

In 1911, Peyton Rous discovered a chicken tumor which not only can be propagated indefinitely by transplantation from fowl to fowl—and hence a true cancer—but also can be induced by a mysterious agent or chemical extracted from

the malignant tissue. In these labors. Dr. Rous collaborated with James B. Murphy, now Director of Cancer Research, Rockefeller Institute.

As such facts were brought to light, and the minds of cancer experts: Is a single substance involved—a lone fearful chemical which causes cancer? Great hopes, too, arose. Is the hypothetical chemical the sole cause of cancer Parhaps, it was speculated, the cause of cancer fact rall, simple—and the cure likewise simple and near at hand. These hopes have been dashed. In their place, how

ever, are definite advances toward the vast secret—for all that, the secret seems vaster than ever. Hope, if an inspiration to intelligent action, does bring results and newer, more firmly based aspiration.

In 1915, two Japanese esientitas, Yamagiwa and Itchitawa, set forth a fundamental experiment. They repeatedly applied coal tark to the ears of rabbits. Malignant growths developed. Coal tar does indeed induce cancer. Yet coal tar is noted for the inestimabily great variety of its components. To determine the guilty substance or substances would seem a herculean lahor. Nevertheless, many investigators rushed to the task

A decade later, in 1924-1925, E. L. Kennaway, of the Research Institute of the Cancer Hospital, London, produced cancer-inducing tars in the laboratory in one matance by heating acetylene in an atmosphere of hydrogen under pressure. Then an ambitious program of detective work was plotted at the Institute—for Kennaway's discovery indicated the probable chemical nature of the cancer-inducing material. Acetylene is a hydrocarbon, and the technici of the experiment apparently should yield only hydrocarbon derivatives of excetylene. Her was a priceless clue.

One by one, the known hydrocarbon constituents of coal tar were tried out on mice--a laborious procedure, involving months of work with each substance. Negative result followed negative result. The years began to go by All the known fractions were separately tested, in vain Still, the guilty agent was there in the tarry mixture-somewhere. A new conception of its potency arose. So rare, so difficult to find, the agent must be astoundingly potent in its action. Minute traces of it, beyond a doubt, could stir up a series of cellular changes having the fatal outcome of cancer.

BY 1930, however, Mayneord and Hieger perfected a special spectroscopic technic by which it is possible to relate the spectra of tars and tar fractions with their cancer-inducing powers. Certain spectra, or wavelengths, were shown to be characteristic of the tarry materials exhibiting the maximum cancer-inducing activity. A special group of chemicals soon became suspect. This group is made up of the more complex compounds of hydrocarbons-known as the aromatic hydrocarbons, and known to feature rings of carbon atoms all tightly fastened together, and with hydrogen atoms clinging here and there; all to make up an intricate molecule.

Particularly suspect was the hydrocarbon called 1,2-bensanthracene, apparently not a cancer-inducing chemical itself, but a molecule giving rise, under the proper spectroscopic conditions, to wavelengths of light impressively similar to those from tars definitely potent cancer-inducers. A logical step was next taken. Why not try the effect of chemicals having molecular structures very much the same as that of 1,2-benzanthracene?

The detectives were able to write down the formulas of the chemicals

Treatment of a cancer with radium. During perhaps half an hour this trestment may continue, the patient feeling no particular sensation

most suspect. The substances were rather numerous and many had never been seen. Dr. Cook rose to the occasion. He synthesized the desired undiscovered substances—a brilliant achievement because of the complexity of these many-runged aromatic molecules. He also made available to this colleagues, by additional syntheses, the already discovered, essential molecules.

As luck in scenece would have it, howver, the first cancer-inducing agent to be turned up was not among those hydrocarbons which Cook's originality enabled him to synthesize before any other chemist. This fact detracts nothing from Cook's extensive pioneering which has turned up dozens of cancer-inducing molecules.

Alert and co-operating remarkably, Kennaway, Mayneord, Hieger, and Cook in the course of their researches reached an utterly formidable molecule-also formidably named, 1,2,5,6dibenzanthracene. This substance they dealt with as they had with the others before. They dissolved it in benzene to make up a 0.3 percent solution. Twice a week they applied a drop to the skin of the backs of their mice. The weeks ran into months. Finally, in a large number of mice, small warts developed on the skin. The warts began to grow, many swiftly. Several frequently coalesced into a single horny mass, which, as autopsy proved, would push forth tentacle-like, hungry tissues extending down into the inner normal tissue.

When, in the future, history is written with the correct perspective, the year of this observation, 1932, no doubt will mark the start of a major epoch in man's effort to survive on his planet.

And, according to Howard B. Andervont, of the United Public Health Service and Harvard Medical School: "This epochal observation, which was the outcome of a series of brilliant experiments performed by the English workers, is an example of the results that may be obtained by co-operative efforts."

D.R. Andervont adds: "It is also an example of the way in which observations made in the one field of science may lead to important advances in other, unrelated fields, for the chemists who first synthesized 1,2.5.6-dibenzanthracene were not interested in cancer research." In 1929, an organic chemist, Clar. had reported a new and ready means of making this compound, with which chemists had been familiar for some time.

1.2.5.6-dibenzanthracene, however, soon lost its unique status-as the only known cancer-inducing molecule. Our Englishmen speedily found that 1,2benzanthracene also was cancer producing, though only feebly so They identified the active constituent of coal tar in 1933: a chemical termed 1,2-benzopyrene. And, in the past few years, from their London laboratories has come a list of more than 30 chemicals clearly cancer-producing when painted on the skin of mice. All substances giving rise to occupational cancer contain a certain percentage of one or more of these agents or of their chemical kin.

Has the cause of human cancer been discovered at last? Not by any means. Dr. Cook states:

"We are not, of course, justified in inferring that human cancer is of chemical origin. All we can say is that there are a large number of experimental observations which are consistent with the view that the factor which initiates the onset of malignancy may in some cases be a chemical compound or compounds."

The very recent story of the developing science of cancer-inducing chemicals constitutes an amazing justification for Dr. Cook's judgment. The story creally stupendous—it involves wholly unexpected relationships among life's highly diverse chemicals, relationships that are as profound as life's deepest secret. It appears that the enigma. What is life?, will as readily be solved as the enigma. What is cancer?

What mystery is deeper than that of sex? The discovery of some of the chemical messengers, the hormones, which play powerful rôles in the development of man and woman has only

made the mystery more involved-despite popular rumors to the contrary. Now the mysteries of sex and cancer have been united. Now workers in the United States become the pioneers. Edgar Allen, Professor of Anatomy at Yale University's School of Medicine. with Dr. E. A. Doisy, in 1923 showed that female sex hormone injections can start certain tissues growing with astonishing rapidity. Also at Yale, and collaborating with Dr Allen, other investigators-G. M. Smith, W. U. Gardner, L. C. Strong, and W. O. Nelsonhave advanced far along these lines. The English school has reciprocated by establishing that some of the known cancer-inducing chemicals can, in special cases, act upon the body in the very same way as certain sex hormones!

ACASSAGNE was the first to report L (1932) the production of true cancer by use of sex hormone. Mammary tumors developed in made mice after a lengthy series of injections of estrin, a female sex hormone. Large doses are required.

"This is a very significant observation," says Dr. Carl Voegtlin, Chief of the National Cancer Institute, United States Public Health Service, "since Little reports that in over 5000 mice in his colony spontaneous mammary tumors occurred only in the females and not ma single male."

Incidentally, the males take on certain female characteristics—and, like true cancers, the mammary growths can be transplanted from the feminized males to either males or females. The cancers, Dr. Allen and his co-workers inform us, after transplantation will continue to grow without additional stimulation (by injection of more hormone). Hence, we must not forget, the genetic or hereditary factor may always play a part in cancer, however induced. This consideration is a whole science in itself—another imposing history, fascinating too.

Not only mice respond to sex hormone injections Such injections produce abnormal growths in rats, guinea pigs, monkeys. Some of these growths are typical cancers. Recently, the American Medical Association warned against the use of a certain cosmetic containing female sex hormone and pointed out the possible production of cancer by repeated application of the cream. The Association has also warned against promiscuous injections of female sex hormone in therapeutic measures. There is no doubt that human beings would ultimately develop malignant growths subsequent to long-continued treatment with such chemicals. Clinical results-in which non-malignant growths have begun to show up just before treatment was halted-confirm these forebodings. (The non-malignant growths cease development and generally recede harmlessly enough upon cessation of administration of hormone.) Where the unified investigations of sex and cancer will lead, none can predict. The future is unimaginably

There is a strikingly close resemblance between sex hormones and the particular cancer-inducing hydrocarbons dis-

The X ray in action for treatment of stomach cancer, 1,000,000 volts now being used to get deep penetration, also to minimize skin burn

covered by the English scientists. Some of the cancer-producing compounds have hormone-like activity. Other physiologically active chemicals—including vitamin D—have molecular structures also strikingly like cancer-causing chemicals.

And so, naturally, there has arrsen a theory that, in some weird fashion, the normal course of chemical transformations within the tissues may be upset and, out of an essential hormone or allied chemical, cancer-producing chemicals may disastrously emerge. This theory is still, for all its apparent plausibility, little more than a guest

Y there are other lines of approach to the problem—and they suggest the theory of Dine of the most powerful cancer-producing substances is methyl-cholanthermone to the acids found in bile has a nonlinear producing substances in methyl-cholanthermone on the discussion of the producing substances are of the acids found in bile has a nonlinear producing molecule. The biochemist readily makes methyl-cholanthrene from bile meth

There is even more to puzzle us—in fact, tremendously much more. A wazlike substance, cholesterol, is present in every cell of the human body; bran and other nervous tissue are especially rich in this chemical. Cholesterol is a member of the chemical family—of related or closely similar molecular structures—to which bile acids, sex hormones, and cancer-inducing chemicals belong. Now to this group of almost belong. Now to this group of almost uniquely strange things we must addate the biochemists above us—such out and the proposed of the

Four Japanese scientists-Yoshida, Otsuka, Nagao, and Kinosito-have made outstanding contributions to cancer lore. Their successes too, nevertheless, have served only to increase the entire mystery. Yoshida demonstrated that the Scarlet R molecule, used to accelerate the healing of wounds, can be burst to yield a cancer-producing molecule, which he identified. In a sense, it was disappointing to learn that this carcinogen is not a hydrocarbon-and so is not a member of the family of the carcinogenic hydrocarbons. The future would have looked much brighter if nature had decreed that only one general type of chemical can be cancerproducing. Many utterly different classes of molecules possess the dire Dotency

IN fact, the so-called "azo compound" of Yoshida does not mduce malignant growth of the skin where presently applied or even where to receive The azo compound, fed or invected, concerned the liver and bladder. According to Dr. Cook, a related azo molecule "was shown by Otuka and Nageo to have a much more pronounced carcinoscine cation on the bladder when administered to rats with their food, but no longer gave cancer of the liver." A subtle change in molecular structure makes a great difference.

Startlingly enough, Kinosita has shown that "butter yellow," a dye hitherto useful in coloring butter and other foods and similar in chemical structure to Yoshida's carcinogen, induces liver tumors in rats. Presumably, butter tumors is discontinued in the similar of the foods has been discontinued.

Today more than 50 different cancerproducing chemicals are known. Is there any property common to them all—besides, of course, their carcinogenic activity? No. And we can be sure that, in the gloomy light of the measurcless dread of cancer, every connectiable property has been considered.

Is there any indication of how these substances produce cancer? No.

In a recent lecture subsequently published in Science, Dr. Carl Voegtlin gives us the conservative, present conclusion: "It seems wiser for the present to admit our ignorance concerning the mode of action of carcinogenic agents."

Man — Mechanical Misfit

In the Long Course of Organic Evolution Diverse Experiments Have Been Tried, Some Successfully and Some Not . . . Is Man Destined to Failure?

By G. H. ESTABROOKS

TATURE is not infallible Far from it. She blunders along for a trifling 300,000,000 years to produce a gigantic race of dinosaurs-then scraps the lot She puts in another 100,000,000 perfecting a type of mammal that makes the elephant look like a pygmy. Then, in a huff, she packs him off bag and baggage to the realm of fossils. The last 20,000,000 years she has been specializing on man and his ancestors. There are many of us who feel that she is just on the verge of losing her temper with this latest product. It may be a guilty conscience, but at times she seems to send in our direction what can only be described as a very dirty look.

However, we are not interested here in ccounting the story of evolution. Rather we wish to draw attention to certain enumering problems with which nature found herself confronted. The production even of man is a tremendous feat, for the engineer builds with only one type of brick, the cell; and there are many billions of these in the human body. To be sure, they differ much from one another in form and function but they are still cells, microscopic in size, from which nature finally constructs such monaters as whales, elephants, or men.

Let us take a very brief glance at the nature of the animal. Fundamentally he is just a gasoline-carbon-burning engine and its basic problems are few in number. When carbon burns it simply unites with oxygen, produces energy in the form of heat and leaves certain waste products behind. So nature's great problem in building an animal-engine really subdivides into three smaller posers. First, get the carbon (food) to the engine. Second, guarantee a source of oxygen and, third, remove the waste. Three neat little problems on which nature has been working for 2,000,000,000 years and is just getting warmed up, so to speak. Of course, there are minor considerations as well. She has spent a great deal of time and energy perfecting the machine, as such. Also she has had to devote much "thought" to its protection, for some animals find tha the easiest

possible way to collect a supply of food is just to eat up the fellow next door Not all these problems have been of equal difficulty. At times we can see where the whole course of evolution has been held up for one or two hundred million years while nature's experts were trying to invent a auitable carbureter, or were completely changing the ventilating system. The fuel pump (heart) has caused no end of worry and the exhaust system (kidneys) is continually causing labor trouble. Yet, for all that, the machine runs and probably will be running hundreds of millions of years from now.

TAKE the question of the fuel supply. Difficult, to be sure, but not as serious as some of the others. Nature's first animals were tiny microscopic blobs of protoplasm The ameba is a giant compared with these first attempts, but if we put it under our microscope we find that its food problem is simple. Its body literally flows around a particle of food, which then passes right through the body wall into the body itself and is there absorbed into the tissues. None of this nonsense about stomachs, mouths, livers, or such things. But life became more complex and, even in these singlecelled animals, we soon find a definite "mouth" appearing and a stomachreally a food sac. For hundreds of millions of years nature was quite satisfied with this arrangement. The animal took in food through a definite opening, digested it in this food sac, and then expelled the waste through the same opening. The sea anemone with its waving tentacles is an excellent example of this stage in the food question, although this method applies also to much larger creatures such as the jelly fish and the Portugese Man-of-War. But it was inefficient, especially when we came to larger animals.

Much more practical was the continuous digestive tube which nature first brought in with the roundworm and has used for the past 700,000,000 years in all higher models. Here the food comes in at one end of the body and follows a continuous course until the waste is expelled from the other extremity. This is one-way traffic and nature could then add livers, kidney, bile ducts, and various types of glands all along the passage, guaranteeing the proper digestion of the food, the elimination of waste, and no worry about congestion caused by back traffic.

This matter of getting food in and waste out of the whole body was not such a serious problem. Somewhat more of a poser was the question of distributing the food, once it was within the body walls. In very tiny organisms nature trusted to the principle of diffusion: the digested food would leak through from one cell to the other. But this had very definite limits. As the animals grew larger she tried the idea of side tubes going out from the central stomach These would convey food to distant parts of the body and then diffusion could get in its work. This idea was better but also called for improvement. In anything larger than a small worm it did not give satisfaction, especially in so far as waste products were concerned. So nature took a tremendous step and installed a fuel pump (the heart) which forces the food in under pressure and literally washes out the debris.

This fuel pump and the fuel lines (blood vessels) have been a continual point of worry to Mother Nature, with continuous alteration in design. The earthworm has half a dozen of these hearts, which are really only thickened and muscular arteries. Since then, na ture has followed a continuous evolution until we come to the very complex four chambered mammalian heart.

The matter of getting food into and through the body was, however, simple compared with the problems involved in the oxygen supply. Carbon is worthless as a source of energy unless an adequate supply of oxygen is always on hand, but how to get it into the body and then guarantee that each of the billion cells would get its share? All life started in the water and there is plenty of oxygen dissolved in normal water supplies. Nature's first answer was again to depend on the principle of diffusion. Gases or liquids will always tend to equalize pressure, if possible. There is less oxygen in a cell than in the surrounding water, so the oxygen in the water, because of its greater concentration, is pushed through the very thin cell wall into the cell itself. Once inside, it unites with carbon compounds, forming the gas carbon dioxide, CO,. This is in much greater concentration within the cell than in the surrounding water, so the CO₂ is pushed out again—a very neat little arrangement whereby the cell in question is assured of an adequate supply of oxygen.

However, this principle has very definite limitations. The cell or body wall must always be moist and must he very thin, otherwise this exchange of oxygen and carbon dioxide will be so hampered as to be inadequate for the needs of the animal in question. An animal the size of even a small fish needs such a thick skin to hold it together that diffusion is impossible, so nature found herself neatly checkmated in the matter of evolution until she could answer this prob-

lem of oxygen supply. Here nature showed real genius. She already had installed a fuel pump in these primitive animals, which guaranteed a supply of blood-carried food to every last cell. Why not use this same pipe line system to get the oxygen around? Only how? The answer was hemoglobin, a red iron compound which colors your blood. This substance has the peculiar power of forming a very unstable alliance with oxygen. As it passes through your lungs, forced on by the heart pressure, it takes on a load of oxygen and then literally dumps it at whatever cell has the greatest need-that is. the least oxygen pressure. Only, of course, at this stage in the game nature hadn't even thought of lungs. All life was in the water. Lungs were several hundred million years away.

SO nature handed this task of oxygen transportation to the blood stream, in addition to its already important one of transporting food. In some relatively late models, such as the insect, the blood still has no responsibility so far as oxygen is concerned. In nature's improved model it had; but how was she to get the oxygen in the water to make contact with the blood stream? After much fussing about with her old idea of skin diffusion she hit on the gill slit. Here the water flows through the gills of the fish or other water animal, propelled by the throat muscles of the species in question. In these gill slits, as you can see by examining any fish, the blood comes very close to the surface of the body, being senarated from the water only by the thinnest of skins. Here we again have the principle of diffusion. The oxygen is forced in through this skin because of its greater concentration in the water and the carbon dioxide is forced out for the opposite reason, thus guaranteeing an adequate supply of oxygen in the blood stream which transports it to the individual cells. The gill slits are the lungs of the fish, and nature was now able to proceed with evolution, having solved a major mechanical difficulty. Size was no longer restricted by this question of

oxygen supply, formerly a limitation. But increase in size immediately raised another question, You can't have animals 30 feet long which are just smasses of jelly; you must have some form of girder on which to drape this mass of muscle, tissue, and blood Obviously, hose of some sort was the an-twenty of the selection of the what? Should the selection he inside or outside the selection be inside or outside the

THE reader will note that, in the accompanying article, the anthor personifies nature: na-ture thinks, nature makes plans, nature rejects, and so on. The reader is at liberty to take this literally or he may regard it more as a convenient man speaking. Since the time of Darwin the great majority of scien-tists deny outside planning and e the amazingly intricate fitting of parts as the result of millions of years of slow actions. Every organism has the power to make certain adjustments to changes in the environment. It also has the power of adjusting itself while it grows. Organisms also vary from time to time with regard to particular features. Give this variable, adjustable organism, say, 50,-000,000 years and the fossil evidence shows that sometimes (not always) it does take advantage of new opportunities and does advance with the times. Other types remain more fixed and stable than the mountains. The anthor, in his article, selects a few of the hundreds of forms known to science and shows what happened to those that did advance from fish to

Will nature really discipline man? Or will social man with his superior adaptability receptions and head it off? Just at present he is demonstrating (in Europe) the need of the slipper. Is he corrigible? Who know?—The Editor.

water animal in question? This question was so vexing to nature that she did if both ways and then sat back to watch results—is still watching results, in fact, very critically, for if man is chased off this earth the insect may do the job, and the insect has the outside skeleton.

This external skeleton has two tremendous advantages. Physical strength is a question of attachment area for the muscles and the external skeleton affords protection. The lobster tribe and many insects are incased in a shell which is "proof" to animals at their own level.

But, opposed to these advantages, is the problem of weight. If this casing is to be effective, then the animal is slowed up by its weight despite its extra strength. It is like the knight of old without his horse, or the heavyweight wrestler-dangerous customers if they can get you cornered, but not much of a problem if you take to your heels. And nature has discovered that the very best of all protection is speed. A hawk is dangerous to a sparrow but a swallow doesn't even notice him. Both hawk and swallow know he'd be wasting his time if he started on a race. Here many insects have hit a very neat compromise. They cut down the weight of the external skeleton to a minimum and, while they lose its protection, they still retain the great advantage of the additional strength. The result is tremendous speed of movement. But the insect can attain no great size, because of a very primitive oxygen supply system-just a number of tubes or traches going into the body from the outside air.

So nature discovered that if she wanted size—and apparently she too is mibude with this "bigger and better" idea—she had to have an internal skele-ton and a device for guaranteeing an adequate supply of oxygen, such as in the case of the shark. As a matter of fact, the shark is one of our very oldest associes.

But here, as elsewhere, the solution of one problem only led to another. All animal life up to this present had probably been in the water, but there was a lot of dry land and plenty of plant life on itwhy not invade? Only how? Once again that miserable question of oxygen supply held up the whole course of evolution. So nature handed this problem of an air-breathing land animal over to her research staff. Many and interesting were the early models. We have fishes which will drown in water, such as the Siamese fighting fish—it breathes air. Other fishes can leave the water and climb trees by means of their stiff fins. They take a deep breath, so to speak, in the water, close up the gills and hold it for ten minutes while on the land. Then we have a lung fish which can breathe in air when its pool dries up in the summer, but which much prefers water. We even have certain land animals some salamanders-without lungs. They just gulp air into the throat and from there the oxygen diffuses into the blood stream.

NATURE'S ultimate answer was, of course, the lung. Originally this was probably the air bladder with which many fishes are cuipped and whose duty it is to regulate the creature's buoyancy in water. He wishes to come up he inflates the bladder, and vice versalization with the course of primitive lung fishes got the knack of guiping air into this bladder from the atmosphere. Then the oxygen diffused through the thin walle into the blood

stream and we had our first air-breathing

We have come a long way from this primitive apparatus, however. The efficiency of your lung depends on the area of contact over which blood and air can come close enough to insure diffusion. The greater the area the more oxygen can pass into the blood stream. It is self evident that you would greatly increase the internal surface area of a simple bladder-say, a football-if you jammed it full of wrinkled tissue paper. The more you crinkled the paper and the more you crowded it in the more surface of contact there would be-always supposing that you have enough room left for very tiny blood vessels and air tubes to traverse the whole mass of paper. This was nature's trick to improve the lung Whereas the outside surface of your lungs is 16 square feet, so expert was nature at this crinkling process that the actual internal surface of contact is about 170,000 square feet, or over 10,000 times as great. So well has nature supplied you, that large areas of your lungs are relatively inactive. You can, in case of accident or tuberculosis, get along very nicely on one lung, or even part of a lung-provided you don't want to play football and race the engine.

So nature developed the lung and got an animal which could live on dry land. For the first hundred million years he put in the early part of his life in the water, as does the present-day frog. Then the race of true reptiles came along, laying their eggs on land, and so the true land-living species developed. But, before developing these land animals, nature found herself up against another engineering problem-that of locomotion. How were these animals to move? Evolved, as they were, from fishes, nature did not have much to go on, for a fish is pretty helpless on dry land.

But never be it said that nature sidestepped a problem. She took the four man fins of the fish, two in front, two behind, and resolutely set out to develop legs. This idea seems very simple to us today, but the nearest approach nature had arrived at which could be adapted to land use was the single large foot, best seen in the case of the snill. This guarantees progress, but not much progresssent properties.

In fact, now that nature bad produced a land animal, capable of large size and fast movement, ahe did exactly what the human being always does in the enthurs am of youthful ignorance: she overdeveloped and overproduced. Dineasure reptiles—came from the factory weighing up to 40 tons (your largest elephant weighs only ten tons), some of the carnivorous varieties being the fiercest beasts of prey the world has ever seen. The reptiles—invaded the sea and produced literal sea serpents. They even

sprouted wings, a-là-bat, and gave us the largest, fastest, and fiercest natural inhabitants of the air yet to be seen.

nablatants of the air yet to be seen.
In fact, the reptiles run the world. For from two to three hundred million to the years this world wan't safe for even another reptile unless he could move very fast or was so huge and well protected them to be huge and well protected the safe of the property of t

For some reason or other, nature had also manufactured these repules with a minimum of brams. Even the largest of them had a brain no bigger than your fast. They must have been extremely stupid despite their size and fierceness Nature has since been producing models with more and more brain and more brain.

But the real weakness of these reptiles which probably led to extinction was the fact of their being cold-blooded animals. This carbon-burning engine which we call our body as exactly like your auto many respects: it won't, go if it's too cold and it atops if it heats up beyond a certain point. The cold-blooded animal is at the mercy of the temperature, As the thermometer approaches freezing he becomes aluggish, and at freezing weather the machine simply stops. The same applications of the same about the machine simply stops. The same applications of the same about the machine simply stops. The same applications of the same about the machine simply stops. The same applications of the same about the sam

So nature evolved another model, the so-called mammal. She gave him a coat of fur to keep out the cold-or heatthen arranged an internal combustion system which works always so that the engine is continually warmed up. Not only that, but, in every species of mammals, she established an automatic thermostat. The human engine works best at 98.6 degrees. Any variation by as much as one half of one degree is a signal of engine trouble and for the services of a mechanic-no disrespect intended to the doctor. Just to make a good tob of it, nature established the same mechanism in the newly evolving race of birds. Then she stood by to watch results.

The new machine proved its superiorly in decisive fashion. Very soon the mammals and birds ruled the roost just as ruthleasly as had the reptiles. Then nature repeated ber old mistake—bigger and better, but bigger at any cost. She developed mammals, such as the long extinct "thunder beast," Baluchithertium, of Asus, far larger than the largest elephant. And once again she wiped out the lot.

The trouble with these huge brutes was one of food supply. Every so often climatic changes occur which cause huge areas of the earth to become semi-desert in nature. If we had a severe drought in the western plains for five years, a mouse or a rabbit might survive; for after all, he only needs a leaf

or two and somewhere or other that scant food supply will exist; the rabbits also might die by the millions but enough of them would survive to perpetuate the species, once the hard times had passed; but an elephant needs a hale of hay per meal, and that is something totally different. When drought conditions arrive, the big anmals suffer most. And, if the climate changes, as it has in the glacial spechs when huge areas of the world were covered by ice, all animals are ilable to extinction that cannot adapt themselves to a cold climate or to a hot climate, when the ice fields extreat.

So nature produced her latest model, man. She had learned that even her highly elaborate heat-conditioned manmal had its weaknesses, but she had also found that one of its most advertised features, namely, its brain, seemed really to be of surval value. In modern man she staked nearly everything on brains; for, as a machine, he is a joke His naked skin gives absolutely no protection against the weather He can't run rapidly; a tiger can eatch him in a twinkle And by himself he can't fight; any carnivorous beast his own weight can serve him up as preakfast to the cubs.

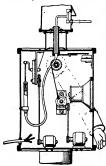

Though early man was much tougher than modern man, his best hope was his wits. Cornered, he sezzed a stick, and found his first club. One day he threw the stick and invented the spear. When the glaciers crept down he wrapped himself in a buffalo skin and discovered clothes. Somewhere he stumbled across fire. With skins, fire, and some sort of shelter he could let the blizzards blizzard if he didn't starve to death. But he didn't. He got the run of the seasons and learned to store food when the hunting was good against the lean winter period

THIS last child of nature became literally a brain child. It has long been a commonplace of parental experience that bright children may need a little discipline, and it seems to many of us that nature is now reaching for the slipper. Her grievances are many but may be summed up in one major charge: man is using his brains to eliminate the fit and to perpetuate the unfit. To qualify as cannon fodder in this 20th Century you must be a physically perfect specimen; while the others live on. Also, we have learned tricks which give us our present differential birth rate, a system which restricts birth in the upper classes, and this may easily yield us a "moronoc-

Any attempt to peer into the next million years merely impresses us with our own ignorance. We can say only that nature, after spending vast periods of time in developing a perfect machine witness the cat—seems to have made a departure in the case of man. He is a mechanical misft.

Automaton Salesmen

A UTOMATONS have been constructed by many engineers, in bodies that mimic those of human beings, but these have usually been for exhibition purposes and have been complex mechanisms of wires, photo-electric cells, and other special devices such as numerous push buttons, switches, and

Mechanism of one of the earlier mechanical men, the basic features being typical of many of the designs

relays. Decidedly, they have not been of the type that an advertising department would purchase in quantities for merchandising demonstrations. Automatons to promote sales are, however, now available from a recently formed corporation. They are covered by patents.

Mechanical Man, Inc., will make a figure to advertise any product by attracting the fascinated interest of the multitudes and thereby impressing upon them the particular trade name. More important, the figure may be made, out-

The ingenuity and versatility displayed in the design of the mechanism for these attention-compelling "sales

Top of column: Three small manikins which have een used to advantage in showing styles. Above: A bowing figure made of oil tins and an oil drum, used to greet patrons of garages service stations. At left: One of the cleverest figures so far made. The four-foot hunter holds his gun at rest, his head up and forward. Then, as the pheasant rises, he turns and tilts his head forward, sims and "fires" the gun, and a red light flashes

The penguin (top) puffs contentedly on a lighted cigarette, winks, and moves flippers and head. The girl drum major spins her batons and executes graceful movements

men" is their chief point of interest for the technical man. Their simplicity is, furthermore, most surprising. In all cases—whether the figure be small or large—all the action is powered by a fractional horsepower electric motor. Reciprocating movement of parts of the body is accomplished by rod linkages between disks driven by worm gears or pulleys. Adaptations of this simple principle give the designers an endless variety of possible combinations. A simple pump with a crank-operated pison supplies the suction, through a small tube, for puffing a cigarette.

A MONTHLY DIGEST

Conducted by F. D. Mc HUGH

ANTHRACITE ASH IMPROVES SOIL

PENNSYLVANIA anthracite ash has long been used to improve soils, but exact scientific data on such utilization were made available for the first time only recently compiling results of experiments conducted at the Mellon Institute of Industrial to Authority of Industrial to king Industrial to Industrial Tolking Ind

"Since anthractic sales are of a nuneral nature," the booklet points out, "their beneficial effect is permanent. In this respect they are superior to humins or other organic materials which tend to disappear from the soil in several years' time. A still further advantage is that humis and soil-conditioning materials are expensive, while Pennsylvania anthractic sales are readily available.

Contributing Editor ALEXANDER KLEMIN

CANCER, at least of certain types, is caused by filterable viruses, and thereby Joins a numerous and varied group of human fils including mullpox, influents, influents, and the state of t

Reynals of Yale University.
Fluids from malignant transplantable tu mors of chickens were whirled in the ultra-centriding, based through fine-pored filters, and otherwise treated after the manner of virus-containing fluids in knowa animal and plant diseases. Materials obtained from these canocreduid filtrates, injected into the tissues of healthy chickens, produced typical canoerous growths.

Moving the giant telescope mirror blank to its museum

The 155mm field gun being towed by a track-laying truck

is heavy traffic

In the researches reported by Dr. Duran-Reyala, chicks responded to doses of a tumor wins by developing fatal hemorrhages and degeneration of tissues, without the development of tumors. However, extracts obtained from such chicks produced the characteristic growths when injected into healthy adult fowls—Science Service.

LONGEST-RANGE

FIELD GUN

THE United States now has a field gun any other standard field gun has ever hene fired. Of 155mm caliber, it sends a projectile a distance of 25,000 yards or, roughly, 14 miles, and blasts a hole in ordinary ground 16 feet deep. It has been named the 155mm gun, MI

Development of this gun grew out of a need seen in the World War, particularly at about the time of the first battle of the Marne The noted French artilleryman, General Herr, wrote of the difficulties the French had in retreating under the heavy fire of German guns with no guns which could answer in kind They needed artillery of very long range which could remain far behind the lines and yet paralyze the enemy and harm their morale This would be done by insistent shelling of the main roads of enemy approach, important stations, ammu nition depots, and centers of distribution, and by making their headquarters untenable and demolishing points of observation. Further, these guns were found necessary for bombarding the enemy's roads of retreat, their reserve stations, and supply dumps of all kinds This kind of fire was called inter-

Hence, there was a demand by the Caliber Board of the United States Army for a gun of about caliber 155mm, with a vertical are of fire from 0 degrees to plus 65 degrees; a horizontal are of fire of 360 degrees; a projectile weighing not over 100 pounds; an maximum speed of 12 miles per hour; and

a width and maneuverability which would permut its use on highways on which there ington Many miles of

The 155mm gan has met most of these requirements In weight exceeds the weight limit by 28 percent, as it is slightly over 55 tons 11s overall width is about 99 inches which is somewhat too wide for rapid movement in two-way traffic. On anything had an width provide a severe handicap, Despite these factors, it is an extremely efficient weapon. In action, it will not be called upon to make long forced marches but will be used as our principal instrument for resching the long-range targets mentioned above. It will, of course, he as interest on railways mounts

This new gun is mounted on a six wheel bogic with rubber tires and in the firing position will be lowered to a firm position made by spreading the outrigger spades.

JUMBO CANAL-WALL

TRIMMER

THE fourth and last section of the great
"Yakima Project" is now far advanced—a system of canals, tunnels, flumes,
and siphons which will eventually irrigate

72,000 acres of farm land in central Washington Many miles of this project will be canals of an open "V" shape with concrete walls and beds. To expedite the concreting job, the sides and hed were trammed by a unique traveling machine developed in the shops of the H. J. Adler Construction Company.

This new trimmer rides on a single rail ach canal bank. It is powered by three Ford motors—one on each bank, and the third for the belt conveyor which is loaded by a centrally located bucket elevator. The entire trimmer advances at the rate of a

foot and a half a munute. The sides of the "V" are two 17-foot rollers, studded with hundreds of small proceing teeth or pars. As these rollers, which are made of 12-inch heavy-duty pipe, which are made of 12-inch heavy-duty pipe, are moved along the slopes of the canal, the spirally-set teeth engage every unch of the usrface and sheart it smoothly. The shearing is so complete that no overdaging or any complete control of the control of

EXPLOSIVES

IN the past 12 years, American and Canadian railroads have transported millions of tons of high explosives without death or injury to anyone.

WASTE

AT one of the symposis of the recent metling of the American Chemical Society were discussed some of the more important of the large number of instances where important outstrain or task wastes have been converted through research into raw materials for the manufacture of commercial products. It was stressed that differentiation must be made between by-products in the usual seense and materials which are true waster— —mot only useless but often Involving es-

pense for their satisfactory disposition.

Under this latter classification may be included the manufacture of sulfaric acid and recovery of elemental sulfar from smelter gases, the production of sulfuric

Traveling canal-wall trimmer that rides on rails

acid from the hydrogen sulfide in petroleum still gases, and the recovery of hy-product sulfur from the hydrogen sulfide in illuminating gas. Sulfite waste liquor has become the source of vanillin and a number of other products.

Waste casein finds its way into resins and adheaives; the fermentation readices in the alcohol industry have been converted into cattle foods and the carbon dioxide into dry ice. Potash is recovered from the dusts of the cement industry, and building blocks have been made from the fit sah.

In a sense, the long list of solvents now recovered from gested erived from petroleum represents success in the use of othernies water materials. The same may be said of cements made from blast furnace alag, and synthetic methanol utilizes carbon monoxide present as an interfering substance in gases used in the fixation of nitrogent branch from the same to the same perior of the same of the same of the same type of the same of the same of the same type of material.

LINENS

THE Pullman Company is sometimes called the world's greatest housekeeper. In one year it purchased 220,528 sheets, 157,780 pillow cases, 20,253 tidies, 455,829 hand towels, 24,318 headrest covers, 13,692 napkins, and 3260 table cloths.

CHLORINATED RUBBER

F further proof is needed that American engineers and chemists are equal to or better than European technicians, it may be found in a recent issue of Chemical & Metallurgreal Engineering, James A Lee, writing in that magazine, states that in the few years succe securing the rights to produce chloritated rubber in this country, Hercules Powder Company chemists and engineers have improved the original characteristics and have been exporting chlorinated rubber to the themselves of Europe

VINYON, IMPORTANT SYNTHETIC FIBER

ANOTHER synthetic resin fiber, that can A be turned into lustrons silk-rivaling hosiery, has just been announced. Known as polyvinyl acetal resin, the new fibers are further cause for headsches among the Japanese for they are synthetic, made-in-America rivals for Japanis natural silk. Silk is the largest single export of Nippon to Uncle Sam.

A research team of Carbide and Carbon Chemicals Corporation, including Harold F. Rohertson, Edward W. Rugeley, Theophilus A. Field, Jr., John F. Conlon, C. O. Young, and S. D. Douglas, has been busilty piling up patent after patent on this achievement.

Polyvioyl acetal reain can be produced in fiber as fine as matural silk, virtually as strong, more clastic, waterproof, and fireproof. The basic materials of the tweest fibers are salt, coal, lime, and air. Out of these cheep and plentiful raw materials are made high molecular weight (7000 to 13,000) water-plare rains. The actual production consists of polymerizing vinyl halides with vinyl esters. Among the suggested uses of the new fibers, heides the hosicy field, are: waterproof clothing, bathing suits, fireproof awning which are self-like in appearance, fabing lines, fabing nets and selnes, acid and talki-resistant clothing, electrical mulation, and curtans for shower baths. The new fiber material, to be known as Vinyon, is not yet in commercial production for houser, in 8 rd properties, it is comparable houser, in 8 rd properties, it is comparable although the latter is made by a different chemical method—Science Series.

BIGGEST BUTTER

MAKER

THE largest churn in the country has just been built by the Jensen Creamery Machinery Company, Oakland, California, and installed in the Challenge Cream and Butter Association plant in that oty. It is constructed from two sand-cast aluminum shells which, together, weigh 1500 pounds in testa, this unit has churned 660 gallons of cream into 2580 pounds of butter

Batches of 2580 pounds of butter are made in this aluminum churn

in 30 to 45 minutes Because of the cubical design, the churn is reported to he capable of churning hutter in 50 percent less time than the conventional roll type units.

The huge aluminum castings which make up the body of this new dairy machine were cast at the Los Angeles foundry of the Aluminum Company of America, and are among the largest aluminum castings ever made. The patterns were so large that special doors had to he built in order to move them out of the pattern shop into the foundry for casting. Aluminum was used in the construction of this churn in order to obtain the advantages of the metal's lightness and non-contaminating properties.

NEW REFRACTOMETER

A SIMPLE instrument for measuring the representation of the representation of the General Electric Research Laborator, Though smaller and much less costly than previous instruments, the new refractometer is accurate to two desimal places. The principal parts of the device are a telescope, monated like a microscope, and a pollshed metal prism. One surface of the latter is vertical

Refractometer and its telescope

and another is at an angle of 45 degrees from the axis of the telescope.

As the angle of till is fixed at 45 degrees by the prism, only the thickness of the glass and the amount of displacement of an object viewed through it need to be measured The thickness is measured by placing the sample against the vertical face and taking comparator readings.

Attached to the fulled surface of the prison is a pace of drawing paper on which a large dot has been made with black int. Displace ment is measured by adjusting the hase until the cross-hair of the telescope is annually a servent directly, and then through the test glass. The difference is the optical displacement. With this datum, the index of refraction can be determined by silde rule and reference to table.

For the study of thick glass, the use of a sodium lamp as an illuminant has been found advantageous.

PHOSPHATASE TEST

MADE ELECTRICALLY

ANOTHER atep in making milk safe for public consumption is taken by the Luximeter, a new instrument developed by the General Electric Company to check the degree of peateurization of milk by the phosphatase test.

A chemical test for determining the de-

Milk undergoing phosphatase test

A truck is used for transporting the radio-controlled target plane to and from the anti-sireraft range

gree of pasteurization has been used for the last few years with great success in the Scandinavian countries, and the New York State Department of Public Health has been among the first in this country to experiment with this method of making the phosphatase test. General Electric has been

working in close collaboration with the New York State Department of Public Health for the last year and much valuable data and suggestions have resulted from the efforts

of the Health Department.

The G-E Luximeter, while designed primarily for use in measuring the transmission of the blue solution obtained in the phosphatase test for milk, has many other possible applications. One use in particular to which it may be resdily applied is that of making a turbidity test in water supplies. Satisfactory turbidity measurements have been made over the range of 100 to 3500 parts per million on the silica scale.

The new instrument consists of a light source, a light-sensitive cell, and an indicating instrument, all in one compact unit. The light source is regulated by a rheostat and is directed through a glass tube containing the solution to be measured. The light so transmitted falls on the sensitive surface of the cell where the values are read directly in percentages on a micro-ammeter

Requiring only a six-volt, half-ampere power supply, the Luximeter may be attached to a storage or dry battery, or voltage regulating transformer. The new instrument weighs only two pounds. It may be carried about by milk inspectors on their tours of dairies or used by large dairy owners in testing their pasteurization.

PHOTS

BY the end of 1941, Robert H. Hinckley, Chairman of the Civil Aeronautics Authority, predicts that the United States will have a total of 70,000 licensed pilots.

RADIO CONTROLLED

TARGET AIRPLANE

POR training infantry and field and coast artillery in anti-aircraft gunnery, targets re frequently towed behind an airplane which flies at a relatively low height. These targets are of the sleeve type, resembling the wind socks seen at most airports.

Towing sleeve type targets has many dis-

the small air-cooled engine of the target plane is started and adjusted to the required revolutions per minute. A catapult shoots the sirplane into the air, and flight is maintained by two small propellers driven by the single engine. These propellers rotate in opposite directions so that torque and slipstream effects are eliminated. When, the aerial target has completed its mission and given the ground personnel sufficient practice for the day, the operator directs the little craft to a landing area. He then presses a button; immediately the motor stops and a parachute springs from the airplane. The target floats gently to the ground and is soon ready for another tour of duty.

One of the advantages realized, in addition to the disadvantages eliminated, is the small cost of construction and the ease of maintenance and repair. Even if struck in a vital spot, the target airplane can be readily put back into commission. Again, the target airplane can be operated in a minimum of space, at a place convenient

Target plane ready for launching from its catapult. A two-cylinder engine drives the twin propellers

for any branch of the service. Previously, anti-aircraft practice could be undertaken only in the vicinity of a large airdrome .-

advantages. The targets cannot be maneuvered sufficiently, and they do not simulate the outline of an airplane The pilot of the towing airplane may be struck by a stray bullet-although such a mishap has not occurred to date. Further, the rifle or machine gun personnel on the ground have no way of telling whether their fire would have reached a vital spot of the airplane.

All these disadvantages will be eliminated, and many new advantages will be secured, by the use of a small radio controlled airplane which is in process of test by engineers of the Army Air Corps at t Field, Dayton, with Captain George V. Holloman directing the experiments.

The little airplane is only about one third the size of a normal combat airplane and has a 12-foot wing spread. It is flown at reduced speeds and has a service ceiling of about 5000 feet. The target airplane is maneuvered solely by a radio transmitter controlled by an officer standing in a safe ention on the ground. By means of a small hand-held instrument, similar to the dial of a telephone, the ground officer can cause the target plane to turn, bank, dive, or zoom. giving realistic representation of a maneuvering aircraft.

When all is in readiness for the take-off,

FOUR BLADED

PROPELLER

THERE seems to be no difficulty in increasing airplane engine power almo indefinitely. At least the power of aircraft

Fettr blades for powerful engines

engines seems to go up a hundred horse-power or even more per annum, and such progress has been continuous for at least ten years. The increased engine powers in-troduce a serious difficulty, however, in the matter of the propeller.

To absorb the power of, say, a 2000 horsepower engine, in a relatively small airplane, the diameter of the propeller becomes in-ordinately large. This means a long, heavy, ordinately large. This means a long, heavy, and clumsy landing gear, which is a serious disadvantage. Also, the speed of the enode of the propeller hlades becomes so high as to approach the speed of sound—with consequent loss of thrust and efficiency. As a result of these facts, Curtiss produced the speed of the spe

peller engineers have now replaced the three-hladed airscrew by a four-hladed one. Tests have indicated that this new trend in propeller design is quite satisfactory, though even with the four blades there is some sacrifice in efficiency compared with airdiameter.

The airplane shown in the photograph is the Curtiss P-36A pursuit, which is highly popular with Army Air Corps pilots. The blades of the airscrew are of thin aluminum, and are electrically controlled. The pilot can select the pitch, and then the airscrew can be used as a constant speed propeller.
When the engine stops it is possible to feather the blades fully; that is, to set them completely on edge to the airstream. This combination of characteristics is very useful for reasons which we have discussed in

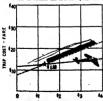

At high altitude the absorption of power of a supercharged engine is still more diffi cult. Some engineers even believe that in addition to pitch control, and four blades, airscrews may need a change-speed gear or even extensible diameter. In fact, one company is already working on an extensible diameter propeller.—A. K.

ECONOMY OF AIR

TRAVEL

THE following figures have been sub-mitted to us by an airline company, whose name we do not mention for ohvious reasons. Even though they come from an interested source, the figures and arguments are so logical and so trustworthy as to deserve full credence.

It is true that air travel fares were once considerably higher than those for other types of transportation. And although rates for air travel within the last few years have

TRANSLESS SALARY-BOLLARS PER HOUR the enemy of serial trun-

been substantially reduced, air travel : still in many cases a higher fare form of transportation. Yet the differential between air and railway travel is not great, and pracair and railway travel is not great, and prac-tically disappears when other expenses are taken into consideration. Thus a round trip hy air from Atlanta to New York costs only \$81.84 and takes only 12 hours. Meals are free and there is no tipping. This same round-trip by rail costs \$58.75 for fare alone. plus an average expense of \$11 for meals and tips en route. And the rail trip takes 45 hours

When salaries of husiness executives are taken into account on a conservative basis, air travel actually becomes cheaper. For a trip of 200 miles, when salaries per hour and time saved are taken into account, the husiness man saves money when his salary reaches the figure of only \$1.18 per hour .-

OIL CONDITIONER

UBRICATING oil in motor cars accumulates impurities such as water, acid. dust, carbon, and metal particles. The heat of the engine plus the oxygen in the air form engine-clogging products generally re-ferred to as "varmah." These resins and tars affect the engine's performance, and in some cases may "freeze" new motors Frequent cleaning of the oil by passing it

Thoroughly clean oil, free from all dirt, impurities, and acid, is delivered to the motorist from this oil conditioner. Dirty oil from the crankcase is pumped into the device, where it filters through a cartridge and is cleaned

through a new device called the Filtermaster will stop the trouble caused by such im-

The Filtermaster, which is made by Clea Oils Corporation, is a simple tank-like affair into which the oil is pumped from a motor-car engine. The equipment does not do an actual job of reclaiming in the or-dinary sense, but does clean and wash the oil of all impurities. It uses a special, re-placeable filter cartridge which absorbs the impurities, and a neutralizing alkali to cou teract the acidity of the oil as it passes

The machine ordinarily runs an average of 25 gallons at a time, so that the car owner does not actually have returned to him the identical oil which was pumped from his

The oil conditioner

car. The theory of operation is that a garage owner would either simply swap clean oil for old or make a standing contract with steady customers to keep clean oil in their motors for a specified period at a specified

PAPER COATING FROM CORN

AVAILABLE as a by-product of corn processing, Zein, an industrial protein, gives promise of outstanding usefulness in the paper coating field As a decorative coating for magazine covers, labels, and similar uses, it gives a pleasing surface without the high gloss of some other coating materials. It can also be formulated with a high gloss and is particularly notable for

high gloss and is particularly notable for resistance to scutfing. Commercially produced as a fine powder of slightly yellowish color. Zelin contains not over 2 percent non-protein solids. The potential yield is approximately one pound per bushel of corn.

HEAVY

A CUBIC inch of matter from A a recently discovered white dwarf star, named Wolf 457, would weigh 9000 tons. This is just under the weight of a -the weight of one of our latest Navy cruisers. A partiele of this could not he supported hy any known matter on earth, for it would "sink" through even our strongest metal.

INFRA-RED RAVE SPEED SEED

GERMINATION

NFRA-RED rays have been successfully used to increase seed germination by as much as 50 percent. This is the report that comes from the Leray Corporation, makers of the infra-red lamp which was described in our January, 1939, issue, based upon tests made some time ago by the Sanders-Durling Entomological Service of New

York. These tests indicated a very noticesalle stimulation as well as an increase in germination.

In these tests, seeds were subjected to the infra-red rays from the Leray lamp. This lamp is attached to any 110-volt electrical circuit, and is moved slowly and carefully at a set distance above the surface of the seeds. Ten seconds has been found to the the most effective time for keeping the

lamp in any one position.

The success of these tests indicate possibilities for improving gardens by insuring better germination.

CEMS

THE Smithsonian has just had added to its collection the largest topaz crystal ever known. This crystal, totaling 350,000 carats, compared with the ordinary gem topax of four or five carats, was found in Minas Geraes Province of Brazil.

DIKETENE AND THIODIGLYCOL

DIKETENE, to which the structure of varyl beta acetoloctone has been as signed, was described at a recent meeting of the American Chemical Society, It is a new radiatrial chemical which is now wailsable in commercial quantities. Its industrial importance hear in the valuable products which may be synthesized from it because of its exceptional reactivity.

Of current interest is thiodiglycol, also discussed at the meeting. This chemical is useful chiefly as a starting material for the manufacture of mustard gas. A new method of synthesis from ethylene oxide and hydrogen suifide was described, which is much less expensive than former methods.

UNBREAKABLE WATCH CRYSTALS MELTED INTO PLACE

UNBREAKABLE watch crystals, in use for many years, have had a disadvantage in their inability to exclude dust from the face of the watch since their flexibility

Melting an unbreakable watch crystal into place. Inset shows a crystal, mounted in position, from which part of the surplus plastic material has been trimmed

causes them to bulge and leave open cracks at the edges. A new method of mounting such crystals on watches, developed by Dutcher Bros., Inc., gives a perfect seal at the edges.

This corporation puts the watch into a machine especially devised for the purpose, places an oversized crysial on the watch, and them melis it into place under slight pressure at a temperature of 225 degrees. Fahrenheit. No cement is used, but the melting at the periphery of the crystal seals at to the rough deges of the beet. The surplus plastic material from the edge of the crystal is their tummed off.

FLUID ANALYSIS

BY LIGHT

A NALYSIS of colorless fluids and some colored fluids which appear colorless is a simple and quick process with the new colored fluids which appear colorless. It is a color to the color of t

The Model 10 R-S-photometer utilizes the proved basic principles of apectrophotometry. A control with a linear scale, calibrated from 350 to 1000 millimicrons, from the near ultra-violet far into infra-red, permits selection of any 30-millimicron band to fall on a slit opening into the test chamber. Light from this selected region of the spectrum then passes through the sample

More or less absorption occurs, depending on the nature of the fluid being exsmined. The unabsorbed light as collected in a photocell and quantitatively determined to better than 0.5 percent. By substituting a standard solution in the same light path, the ratio of the light Intensity at the selected wave hand is inducted directly as percent transmittance by any Model 3 Coleman. Electrometer. These results are indepencient of line voltage fluctuations and do not depend on colored filters. These data are precise expressions of fundamental units of color chemistry—percent of transmittance at known wavelengths of viable or invisible light.

VARIABLE POWER

TELESCOPES

GHARP images in steps of five powers, and of the powers are claimed for no 80 brovens are claimed for new telescopes recently an annuared by Wolfersak Optical Company, No one telescope gives this full range though there are as many as its ranges in some of the new telescopes. Under the trade ame of Vari-Power, these telescopes have hurried focusing ring; non-loosening, non-wolfle joints that are dust-proof at moisture-proof; and chrome-plated rust-proof tubes.

PENCILS

NEARLY four million lead pencils and 2600 gallons of ink per year are used by the employees of the steel industry.

BELL-RINGING RADIO

DEVICE

A NEW bell-ranging device, which permits emergency radio call to be put through as easily as telephone calls, has been developed in the Forest service Radio Laboratory at Portland, Oregon. This standby unit has been developed for the new Type T ultra-ligh-frequency radio set, 30,000 to 40,000 kinceyles. Any Forest Service ultra-high-frequency radio set, however even the lightness eight-pound portable even the lightness eight-pound portable—

can call a lookout or other station equipped with this bell-ringing device. Planned primarily for use at fire lookout Business by"-a noise especially annoying during telephone conversations.

by Westinghouse

begins with BUYING

· A manufacturer must buy before he can sell. He must buy the raw stuff that goes to make the finished product; he must buy machinery and the plants to house it, and must hire the men without whom the finest equipment in the world would be just so much worthless scrap.

· In our particular case, being a large manufacturer, we are first of all an enormous buyer. If all of the copper wire we buy in a single good year were converted into sixteenthinch wire, the strand would stretch over 209,000 miles-enough to wind eight times around the Earth. And the insulating yarn we buy could be looped 36 times from Earth to Moon.

· We use enough steel and iron each good year to build two railroad tracks 2,290 miles long-or a couple of Oakland Bay Bridges.

· We buy a lot of gas, oil, hydrogen, nitrogen and oxygen; we are a huge consumer of gold, silver, mercury and tungsten. You won't find the kind of sapphires we use for bearings in a jewelry store-nor would you find a jewelry store in the world that could supply the 20,000,000 jewels we need each year. We even buy dismonds and use them as dies for drawing very fine wire. Though most of our purchases run into tremendous quantities, one of them, last year, amounted to just one ten-thousandths of a gram. That was radium, and it cost \$300.

· Every one of the forty-eight states and Alaska are important suppliers of ours. Twenty foreign countries contribute materials not produced in America. Almost literally, every industry and every farm produces something that we use.

· "What in the world can a farm grow for Westinghouse?", you ask. Just to name a few things - oat hulls. molasses, grain and sugar cane for alcohol, dextrine from corn, flour and straw for making foundry cores, lard, sugar, lumber and tapioca; also leather, wool, cotton and meat products. It all adds up to this. Each vearwe buymorethan \$100,000,000 worth of the products of industry and farmers. Some of our people have estimated that these purchases give work to about 36,000 persons annually. This is in addition to our own 43,000 employees who fabricate these materials into a vast number of machines and appliances which increase the permanent wealth of America.

· Who gets this wealth? Why, the industries and farmers who sold the materials to us, of course. It's really nothing but an elaborate process of swapping. We swap what we make for the materials needed to make our products:

· That's why we cannot consider ourselves as a separate industry. Along with thousands of others, we are merely an essential cog in the tremendous process which has created American prosperity and the American way of living.

towers, ranger and dispatcher stations, this device will eliminate the constant noise from loudspeakers when operators are "standing

Lookouts and other forest officers will no longer need to stay close by their radio sets waiting for calls, as the device may be adjusted to carry signals to men working outside their stations. Lookout men can be aroused from sleep by the ringing bell if a night-look for fires in their territory is required. A series of code-rings is possible when several stations are included in any one Forest Service network.

PORTABLE METAL FIRE ESCAPE

NEW fire escape which combines the strength of a permanent fire escape with the portability and case of handling of a rope ladder is shown in one of our illustrations. A product of Engineering

Development Company, this unit may be anchored on any window sill without diffi-culty, and then dropped to the ground as one would drop an ordinary rope ladder. In the 16-foot length for a two-story buildand the lottor length for a two-story building, the ladder weighs 15 pounds, while in the three-story length—24 feet—the weight is 20 pounds. The load capacity is 1800 pounds, and each rung, which is built in the form of a stirrup, has a footing of 4 by 91/2 inches.

FIRST YEAR OF THE CIVIL AERONAUTICS AUTHORITY

T was quite appropriate that at the com-pletion of the first year's work of the Civil Aeronautics Authority, Chairman Robert H. Hinekley should make public a statement as to its own activities and those of civil aviation as a whole, which, from every point of view, have been highly againfactory.

In June, 164,578 passengers were carried, or 64 percent more than in the corresponding month of 1938. During the first six months of 1939, 1627 airplance were pro-duced, while in the same period for 1938

QUANTITIES LIMITED-ACT QUICKLY

For sale by SCIENTIFIC AMERICAN, 24 West 40th Street, New York, N. Y.

only 850 civil aircraft were constructed. Today 26,144 pilots hold certificates, or 6000 more than a year ago. There are 11,160 certificated airplanes or 1400 more than a year ago. Even without the C.A.A. pilot training there should be 36,000 certificated pilots by the end of 1940, and 43,000 by the end of 1941.

Federal airways have been increased to a total of 25,000 miles, with improvements in aids to navigation more than keeping

The C.A.A. flight training program will give us 10,000 student pilots next year.

The Washington airport at Gravelly

Point is beginning to take shape, with work proceeding rapidly under the supervision of the Corps of Engineers of the United States Army.

The existing system of scheduled airmail carriers is now legally a public utility. Cer-tificates have been issued which make the existing airlines secure in their positions and free to plan for further progress.

The safety record of the airlines has been remarkably good. They flew 72,900,000 miles per pilot fatality; 51,700,000 passenger miles per passenger fatality; and 24,300,000 miles per fatal accident. These records are nearly three times better than the same records for the year 1938.

Technical developments have been equally assisfactory. Ultra-high frequency radio ranges operating at 63 and 125 megacycles at Indianapolis and Pittsburgh have been proved to be free of static whether from natural or artificial causes. This freedom from static, particularly in bad weather, is one of the most important elements in air transport radio communication and safety. Contracts have been let for three units of a new and approved type of ground direction finder. The blind landing system nearing completion at Indianapolis is one of the most comprehensive yet devised.

The Safety Board has developed its methods of accident investigation, with hearings conducted at or near the scene of the accident within a remarkably short time thereafter. The publication of reports after such investigations has given aircraft constructors and operators much valuable information .- A. K.

CHEAPER COPPER

PROTECTION ON

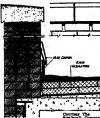

FIBER BASE

C OPPER has been valued as a protective metal in building construction for many centuries. However, its high cost milimany centuries, rowever, its night cost min-tates against its use in many places where it would do a superior job of protecting against leakage or dampness. At least two companies—The Sisalkraft Company and the Angier Corporation-have provided an inexpensive product for use in all types of flashings, which combines the protective value of a very thin copper sheet with the strength and body of an adherent impresnated fiber.

Both of these companies use very thin sheets of pure copper completely free from pin holes, produced by electrical deposition

of the copper on lead drums.

In the case of the Sissikraft product, this thin sheet is bonded under heat and pressure to their own tough product celled Sissikraft. The resulting sheet, which may be made in different thekenesses for different sapislar.

How thin sheet copper, bonded to a fiber hase, is used to waterproof a parapet and damp-proof the insulation under built-up roofs

tions, is flexible, will not kink or crack, can be cut to fit with ordinary shears, and is casily bent to place by hand. The Angier Corporation's product, called

The Angier Corporation's product, called Copperskin, is backed up with tough and durable paper to provide the advantages of regular 16-unce copper at approximately one fifth the cost. The backing material is called Brownskin, is resilient, and can stretch or shrink with the expansion and contraction of the copper due to temperature changes.

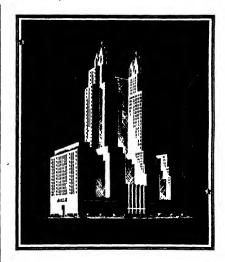

FROZEN SOLAR ENERGY

FLORIDA sunshine shed its glow at the New York World's Fair one day, playing a rôle in ceremonies at the Florida State Exhibit Building. Flown from Jacksonville in mert form, the sunshine had been abworhed by luminescent powder and "canned" by being frozen in liquid air.

The feat of rendering solar energy inert, then transporting it nearly 1000 miles and releasing it, is believed to have been accom-

De Luxe Library Editions of SCIENTIFIC AMERICAN

Make them yourself; protect and preserve your copies with a PERMO LIFETIME BINDER It holds a year's issues

SO MANY readers preserve their copies year after year and have asked for binders that, after theough investigation of binders, the editors of Scientific American found a type that is most sainfactory, considering cost, ease of handling, and durability. It holds a full year's issues (12), has an efficient patented lock; is strong and durable; and is covered with a rich, pibbled, red leathersthe beautifully sampped in gold. Magazinies are bound in with a empt and are held positively in place; no punching necessary. In ordering, state what year (1998, 1999, etc.) is to be earnipped in gold on the backbone.

Each \$1.50 postpaid in continental U. S. (\$2.00 postpaid elsewhere)

SCIENTIFIC AMERICAN, 24 West 40th Street, New York

plished successfully for the first time. It was directed by Samuel G. Hibben, lighting engineer for the the Lamp Division of the Westinghouse Electric & Manufacturing Company.

In absorbing light energy, scientists beheve, the luminescent powder actually undergoes a temporary change in physical structure. The theory is that the outermost orbits of electrons, which make up the molecules and atoms of the powder, are distorted or literally moved from one energy level to another when excited by impinging light, actually imprisoning some of the light,

Then, just as a piece of sponge rubber aprings back to its original shape on being released from the hand, so do the electrons tend to return to their normal positions, and in so doing, give out the light energy they have imprisoned.

ELECTROMETRIC pH STANDARDS

TIME-SAVING capsules of chemicals in powder form are now available for use as reference standards for checking electromeine pH apparatus. The "Hydrion" Buffer Standards, as they are called, when dissolved in the proper amount of distilled water, make solutions, the pH of which have been electrometrically checked by the menufacturer Five different standards are offered, ranging from 3.0 to 9.2 in pH value.

STORYTONE

AN electrical musical instrument that cap-tures all the richness of tone, volume, and color of the grand piano and is housed in a cabinet no larger than a spinet, has been developed by RCA engineers in col-laboration with craftsmen of the Story & Clark Piano Company The new instrument will be marketed through Story & Clark dealers under the name Storytone "Voiced by RCA Victor."

Providing the music of the piano, the radio, and the phonograph, the Storytone utilizes specially designed electrical amplifying and speaker equipment to reproduce the full range of tones with sparkling clarity and brilliance. The volume is easily con trolled by a single knob located at the end of the keyboard panel. The range is so flexible that a single turn of the knob produces the softest whisper of a note or brings forth the full tonal blend of a powerful crescendo

When the volume control is adjusted to conventional piano range, the Storytone rivals the largest concert grand piano, and when the amplifier is turned low or completely off, a pleasing harpsichord effect is produced. In addition to the customary "damper" and "soft" pedals, the instrument is equipped with a "swell" foot pedal with which organ effects may be produced through regulation of the amplifier volume.

, Bench of the Storytone, opened

Used in conjunction with either a radio or phonograph, the Storytone reproduces radio programs or recorded music. A special piano bench has been designed which contains a radio and phonograph located separately in two sliding drawers placed directly beneath the seat. A simple plug-in connection per-

mits essy operation of either instrument. The

Storytone may also be played while the rsdie or phonograph are in operation.
Unaffected by either temperature or hu-

undity changes, the instrument's tone is developed electrically through a seven-tube amplifier of 20 watts output. Set in motion by the percussion of the striking hammers, the mechanical vibrations of the strings induce corresponding electrical vibrations in the coils of magnetic pickups. These electrical vibrations are then amplified by radio tubes and converted into audible musical tones by a powerful high-fidelity loudspeaker.

JUNIOR ARC WELDER

FOR garages, blacksmiths, construction engineers, machine shops, and others, a new 200 ampere arc-welding unit, either belted or direct-driven, has been developed by the Lancoln Electric Company A compact unit, with its own control board, this welding unit weighs approximately 320 Dounda

OLD BUILDINGS MADE FIRE RESISTANT

OUR out of every five deaths caused by tenement house fires-that annually take a toll of hundreds of lives in American tities-esn be prevented.

A four-year campaign by the New York building department to make Old Law tenements more fire-safe, has succeeded in reducing the number of deaths resulting from general conflagration in them from 38 in 1934 to 7 in 1938.

The campaign, backed by State legisla-tion, is an effort to make the average Old Law "tinder box" into a more fire resistive building by requiring that it be equipped with a fire-resistant cellar celling, fire-retarded stairwells, and modern stair-type fire

The total cost of all three improves according to general estimates, is about \$50 a family—inexpensive and permanent

life insurance for the families protected. Fire-retarded stair halls, the basis of the contribution to Suilding safety. It is an attempt to make the ordinary wood student plants and plaster stain-hall walls of the average

tenement house more fire-resistant so that they can confine the fire to its place of origin instead of serving as a glast fine for the flames from first floor to roof.

Various methods of fire-restarding are today approved by the New York Building Department. The simplest method, how-look the service of the service of existing construction. Widely used in New York City, it employs granulated mineral wool, a fire-proof insterial with excellent heat-topoping properties that has been used heat-stopping properties that has been used for many years to insulate the roofs and side walls of building against heat and cold

This same material is easily adapted to stair hall fire-retarding. Small holes are cut into the existing plaster and the mineral wool is then pumped into the hollow partition to a pressure of ten pounds per square inch. The result, which complies with Department standards, is a five and a half inch wall with a thick inner fireproof core By effectively withstanding a temperature of 1700 degrees, Fahrenheit, for one hour, such a wall prevents the spread of the fire and permits the safe evacuation of the building.

STEEL

DURING 1939, the research program of the steel industry congram of the seet money; of templates a total expenditure of approximately \$10,000,000. This is 15 percent more than the total of \$8,700,000 which was spent for the same purpose in 1929.

120,000 PICTURES PER SECOND

WHAT is believed to be the fastest camera in the world, shooting 120,000 pictures per second, does not employ glass-lenses. Instead, it has 1000 holes .01 of an inch in diameter, or approximately the size of a pin hole. The drum-like camera is used in the study of electrical arcs so that en-gineers may analyze the behavior of such arcs in circuit breakers and other electrical apparatus.

The cylinder is 14 inches in diameter and is driven by a ½-horsepower motor which speeds up to 7200 revolutions per minute. At such a speed, each of the 1000 pin-hole

The pin-hole drum, carrying film of the high-speed camera, revolves behind opening at right center

openings is open for only 1/120,000 of a second. The size of each of the 1000 pictures taken by the camera, with a single film, is nine millimeters square, or about one third

of an inch on a side. While intended primarily for the study of electric arcs, other applications for this camera may be found.

THE CHEMICAL STRUCTURE OF VITAMIN K

CHEMISTS working independently at two different institutions, Harvard University and Saint Louis University, have determined the structure of vitamin K, the blood-elotting principle. The structural formula, according to the chemists, is 2-methyl-3-phytyl-1, 4-naphthoquinone.

The synthetic vitamin was checked by comparing spectra, color reactions, anti-hemorrhagic activity, and chemical prop-erties, with those of the natural vitamin obtained from alfalfa.

The synthesis is declared to be an efficient and practical one suitable for manufacturing purposes, and the pure vitamin is thus made available for use in medicine to prevent and control hemorrhages.

VERSATILE DEHYDRATOR

THE Henry Cartridge Dehydrator, originally designed for air conditioning and refrigeration, is finding increasing use where need exists for removal of moisture from chemicals in solution, and in air drying. The major features of this Henry dryer

are its patented dispersion tube and re-placeable dehydrant curtridge. The per-forated dispersion tube—exposing the en-tire volume of dehydrant to penetration by the fluid or air—extends along the center axis of the dehydrant column. This construction is claimed to reduce the press drop, prevent channeling and resultant loss of efficiency so often found in dryers of conventional design.

Refill cartridges make recharging of these Henry dryers exceptionally simple and easy. Cartridges are available charged with acti-

"FLOATING" BRAKE

LINING

A SINGLE piece of "floating" lining is a novel feature of a new design brake adopted for the recently-announced Crosley This lining is not riveted, but "floats" freely between the brake shoes and the drum, thus affording braking action on both its surfaces instead of only one side as

The lining "floats"

in conventional brakes. An interesting feature of this hrake is the "creeping" or slowly rotating action of the lining, which distributes wear evenly over the entire lining surface, thereby greatly increasing its service life

Should it be necessary to replace the liming after prolonged service, it is necessary only to remove the wheel, withdraw old lining by hand, and merely slip a new length

of lining in place. The brake shoes, which provide about surface, are made of a special nickel-chrome iron sufficiently flexible to conform exactly with the drum contour when braking pres

FALLING DIAMONDS

DIAMONDS actually fall from the sky. That real diamonds exist in meteorites has just been demonstrated for the first time by X-ray examination of hard, black erystals in a specimen from the celebrated Meteor Crater in Arizona.

The present specimen was obtained not long ago by the Smithsonian Institution, and me of the suspected diamond inclusions were ground out. They were turned over to mineralogists of the Geophysical Laboratory of the Carnegie Institution of Washington for study by the most refined methods, with the result that the true nature of the inclusions no longer is in doubt

The conditions under which meteorites robably were formed would be favorable for the formation of diamonds, provided the requisite carbon was there in the first place.

Demonstration that the inclusions actually are diamonds recalls the futile efforts made to drill into Meteor Crater in the hope that a big diamond mass would be encou tered. After drilling straight downward for about 1200 feet the drills struck a resistant

Marlin Razor Blades

Old Company Stashes Selling Costs-Offers 40 First Quality Blades for Half a Dollar

The Marlin Firearms Company, famous for the manufacture of fine guns since 1870, has found a way to bring the finest quality razor blades to shavers at a fraction of their usual cost.

Basic patents having expired, Marlin pays no royalites. And by selling in "whole-sate" quantities, with economies in packaging, shipping, etc., the company effects savings which are passed on to the consumer

Made of the finest Swedish surgical steel, for standard holders, Marlin blades steel, for standard holders, Marlin blades are offered at the unprecedented price of 80 for one dollar, 40 for fifty cents. Under the company's ironclad guarantee, you can try these new blades without risk Use five, and if you do not find them equal to the best, you may return the balance and get your money back

material through which they could not pene-trate. Efforts to sink a shaft were defeated by striking water. Geophysical experiments indicated a very heavy mass in the neighborhood. None of this, of course, would be accepted by geologists as positive evidence of the existence of a large diamond mass. There is even some question as to whether the "shooting star" responsible for forming the Meteor Crater actually penetrated the earth at all. It may simply have exploded and its fragments scattered over the neigh-borhood where many of them have been

picked up in the past century.

The diamonds found in the Smithsonian Institution specimen are not of gem quality. They are very good black diamonds—even more valuable than medium-rate gems be-cause of their use in industry.

SWEETS FOR HIGH-FLYING BOMBERS

SWEET emergency rations may be car-ried by pilots of bombing planes crus-ing at 11,000 to 20,000 feet altitude and ing at 11,000 feet allitude and peering at the darkness of a blacked-out city, to counteract difficulty in reading their brightly lighted instruments. This may be concluded from experiments reported by Dr. Ross A. McFarland.

Adaptation of the eye to dark and light is seriously affected by lowered oxygen pressure, Dr. McFarland and Dr. W. H Forbes found at Harvard University, but the effect can be counteracted by a dose of glucose. The eye fails to adapt normally because the amount of oxygen in the nervous tissue is decreased. The trouble is in the nerve elements of the retina and central nervous system, not with the photo-sensitive substances in the eye .- Science Service.

When you write to advertisers The Editor will appreciate it if you will mention that you saw it in SCIENTIFIC AMERICAN

Inc. It is used for testing plaster, brick, or lac. It is used for testing plaster, Drick, or concrete surfaces before decorating them, or for tracing leaks. It gives instantaneous readings of "dry," "wet," or "very wet." This device is a simple electrical meter with an extension cord on the end of which

is a handle containing two projecting needles. These needles are punched into the surface being tested, thus completing an electrical circuit. The flow of current between the needles and through the wall at that point will thus register on the dial of the meter without any calculations, the amount of current flowing being dependent upon the moisture of the wall. The circuit used is said to insure the highest possible accuracy regardless of whether the enclosed battery is new or old. The dial may be calibrated to meet special conditions.

YAWLS FOR THE NAVAL ACADEMY

AS a result of efforts over a number of years of high Navy officers to obtain up-to-the-minute sail boats for the Naval Academy for instruction in seamanship, the Luders Marine Construction Company

Practical seamanship is learned by midshipmen on yawls such as this

was awarded on their competitive design the contract for building three Navy

yawls: Intrepid, Alert, and Resolute.

Each of these boats is 44 feet overall. 11 feet beam, and 6 feet draft, with 965 square feet of sail and 9000 pounds of lead in its keel. Accommodations are for eight mid-

They are designed to be the last word for ocean racing and are equipped with Diesel ocean racing and are equipped with Diesel engines as auxiliary power. They will give the midshipmen many opportunities to race against civilian yachtemen and are the forerunners of an expected fleet of 12 to 18

THE PROBLEM OF THE WEIGHTS

ONTINUING our series of mathemat ical brain-teasers, we offer the Prob-lem of the Weights. It is, according to the suthor, a paraphrase of one which is over 300 years old, and one of the few really good problems in arithmetic. The answers and the solution will be given next month. Meanwhile any correspondence concerning this or previous problems should be ad dressed to Lieutenant Commander Leonard Kaplan in care of Scientific American, 24 West 40th St., New York, N. Y. All letters will be forwarded unopened.

It is desired to obtain a set of eight weights for a beam balance such as is show in the accompanying sketch. They are to be

used for weighing to the nearest ounce any object up to, and including, 205 pounds. Each may be used on the left scale pan, or on the right, or not at all. The problem consists of three parts as follows:

I) Determine the magnitude of each weight. II) Prove that eight is the least number,

and, that III) These eight weights have the least total weight of any set which will fulfill the conditions of the problem.

Heavy, oily liquid of dark straw color. Evaporates slowly at ordinary temperatures; thus is a persistent type of gas. Frequently diluted with another poison, chloropicrin, to keep it liquid in colder weather. Has a delayed action on body. First symptoms, stching and blistering. Especially damaging to eye's cornes. In eye, tissue degeneration begins two minutes after exposure to dilute concentrations. If gas is swallowed, symptoms of nauses, vomiting, and diarrhea develop. Gas very penetrating. Goes through ordinary clothing, rubber, and even leather. Is 50 times more toxic than chlorine.

Chlorine Gas. First gas used in World War, Two and a half times the weight of air. Clings to ground. Fills shell holes, depressions, and dugouts, Greatest action oc curs in presence of moisture. Major action is on respiratory tract with symptoms of

choking, coughing, and suffocation.

Phoagene Gas. A combination of carbon monoxide and chlorine. Resembling chlorine in action but has a more delayed effect. In 10 times more toxic than chlorine. First symptoms very minor. Its effectiveness mainly due to initial innocuous character. Its mensoe is revealed only after considerable gassing has occurred.

aute gassing has occurred.
Lessistic Chemically, chloro-vinyldickloro-arrian. Developed secretly during.
World War hy Capt. W. Lee Lewis of U.S.
Chemical Warfare Service. War ended just
before gas entexed sembet use. Has all
bilitizing geoperates of masterd gas but

more effective because it has ability to penetrate the skin. Three drops, placed on rst's abdomen, causes death in two to three hours. Is powerful respiratory irritant. Produces violent sneezing. Another variety, bets-beta-prime-chloro-vinyl-dichloro-arsine, has less blistering effect but its irritation on

respiratory system is much more severe.

Toxic smokes. Chemically, diphenyl-chloro-arsine and diphenyl-cyano-arsine.

Popularly called sneezing gas. Are really finely divided dusts. Can pass through ordinary gas masks unless special filter at-tachments are provided. Effective in concentrations of one part in 10,000,000 of air. In higher concentrations, cause vomiting. Considered as poisonous as phosgene in

equal concentrations. Crying Gases. Twenty-three different varieties used in World War. All intended varieties used in world war. All intended to produce temporary dissibility and confusion. Favorite German lachrymatory gas was xylyl bromide. Among the Allies, chloropicrin was widely used.—Science Service.

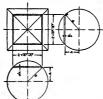

SOLUTION TO THE

PROBLEM OF THE

Intersecting Cylinders

THE problem offered last month was to I find the volume of the material removed from a two-inch cylinder by a two-inch drill. The axis of the drill was perpendicular to and intersected the axis of the cylinder.

Here, as was promised, is the solution The illustration shows the section removed

from the cylinder. The radius of the cylinder is equal to the radius of the hole and has been designated as a.

Taking sections in the manner indicated, the volume, V, will be given by the expres-

$$2\int_{0}^{a} (2\sqrt{a^{3}-r^{2}})^{3} dr$$

$$8\int_{0}^{a} (a^{3}-r^{2}) dr$$

which integrates into

And so for the specific value, a = 1 inch, given in the problem, the volume of material removed is 5 1/8 cubic inches.

YOUR TIREARMS

Conducted By A. D. RATHBONE, IV

INTEREST IN FIREARMS is traditional with American men; science has so developed them that millions yearly find aport and recreation in their use. Hence this monthly department presenting a wide variety of discussion regarding fiveams, their handling, and their accessories. Suggestions from readers will be heartily welcomed—The Editor.

INTRODUCTIONS ARE

IN ORDER

THE brotherhood of nimreds, gun fanciers, and gun hobbyists is one fraternity which particularly and readily leads stiedl to new and lasting firendships. This introduction of "Your Firearms" to Scientife American readers is performed, therefore, with the pleasurable anticipation of capaging with kindred souls in monthly round-table discussions and arguments in leasurable discussions and arguments in leasurable as it? "Your Firearms" we're going to discuss, we will endeavor to class about the things in which you are interested.

about not enling in south report and the season and movement of the season and the season

BIRD SEASON SHOTGUNS

WHEN the old-time angler selects a new trust rod, he doesn't whip it as a David Harum might lay his baggy labe note the old mare's flanks. He picks it up with the same delicate reverence that a pewder imparts to the presentation of a beautifully made watch. He tests the rod's balance; the tip waves gently as, with an easy wrist motion, he gets the general "feel." Your experienced bird shooter handles a prospective shotgum purchase in much the same manner. It's the "feel" of the weapon which tells him what he wants to know

rells him what he wants to know. Incorporated in that "feel," however, are several factors, tabulation of which, to the vetran gunner, are more or less subconscious. The weight, balance, pitch, fit of stock, drop at comb and at hed are all integers which collectively contribute to an instantaneous reaction during the first moment or two with a new gun. The aforesid veteran is entirely conversant with these component items, but he doean't delive specifically into them until after he has applied his first automatic testing formula of "feel,"

Should the reaction he negative, even in the least degree, the piece is either laid saide in favor of another, or the purchaser hefts the gun, tries it rather questioningly to his shoulder again, as if that sliadow of doubt which first crossed his mind might have been an error. The chances are, though, that if the gun "feels" wrong, he can't be presuaded to try it, and if he does, the resultant lack of complete confidence will affect his shooting.

All this applies to the man who knows his guns. How then, to answer the novice, the new chap, who asks: "Which shotgun should I buy?" The logical answer to that one is, of course, another question: "What

The author afield

game do you want to shoot?" But this deasn't give the neophyte much satisfaction. However, we can say that stock fit, portability, trugger pull, gage, gun balance, lince, and certain minor mechanical details are primary features to be considered in selecing a field gun. Let the novice forget momentarily the more technical angle.

Regardless of weight, ager, halnee, or bore the gum must fit the gunner or the results will be disappointing. A beautiful and expensive field piece may be utterly useless if the stock is either too short or too long. The best we can say is to find a gun which feels "right" when it comes up to the properly fitted now sail of climbs—and stay with it long enough to give it an adequate trial. If, then, you can'that what you aim at, take it back for a cheed-up of all phasees.

We have listed portability, or weight, as the second item for consideration because who can walk three or four miles without feeling tired. In our estimation field guns should range between 61/2 pounds and 7 pounds 6 ounces when empty, and while that may not seem like much gun to carry, there are also shells, frequently heavy cloth-ing and, it is to be hoped, some game.

Trigger pull in your shotgun is as imortant as acceleration in your motor car. Both are vital factors in performance and safety, and, just as acceleration in automobiles is not always satisfactory, so in many shotguns the trigger pull will not be perfect. A 4 to 5½ pound trigger pull on a double barrel, 12-gage gun weighing around seven pounds will be found to be pretty close to correct, and although lighter pulls in lighter pieces may be smoother, too much reduction in the pressure brings in the problem of accidental discharge,

As to gages, it is quite universally agreed that the 12, 16, and 20 are the popular sizes in field guns throughout the country. To attempt to designate whether that new gun should be an automatic, a pump, a double barrel, or one of the over-and-unders would be rather like trying to tell the trout fisherman which fly to use. We do feel, though, that if you've been used to rifle shooting, you will find the single sighting plane-that is, the pump, the automatic, or the over-and-under-better suited to you. Regardless of which gun is eventually

chosen, remember, it is like your golf clubs, your tennis rackets, your trout or bass rods. All require constant use and practice to get the most out of them, and that, we might observe in closing, is one reason why we have so many skeet fields.

Pot-Shots

AT THINGS NEW

WINCHESTER AND WESTERN SUPER TRAP AND SKEET LOAD now available in standard shells featuring a new crimp. In this deing a card wad over the shot, these com panies have joined Remington, who an-nounced their new crimped shell last spring.

Using two cameras taking instantaneous ultrs high speed exposures, the two accompanying pictures by flash photography show how the shot charge from the same crimpedhow the shot charge from the same crimpeu-shell load is propelled targetward—from right to left. The upper photograph looks down at the charge from an angle of 45 degrees, while the lower photograph looks up at the same angle. Use of the crimp has eliminated the top wad, conspicuous by its absence in the illustrations, and with no such source of interference to expand or ecatter the charge, there can be no so-called "doughnut" patterns. Attention is called to the Seal-Tite wad, which has served as a pistun, and which is seen dropping away om the charge.

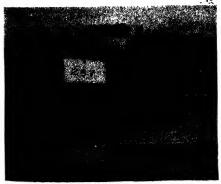

Averages taken from 100 fired 30-inch patterns at 35, 40, and 50 yards showed ow the spread of the original dense pattern center is controlled, resulting in remarkable uniformity of the number of pellets in the outer six-inch ring of the 30-inch targets. The averages were as follows:

Inner 18-inch ring Outer 6-inch ring At 35 yards 218 pellets At 40 yards 172 pellets 160 pellets 159 pelleta At 50 yards 137 pellets 157 pellets

COMBINATION .410 AND .22 is Marlin's latest gun in the over-and-under design. The top barrel takes .22 short, long, and long refle carrindges and features the famous Ballard rifling. The bottom barrel is for .410 bore

3-inch shells and is full chuke, with spe fications similar to the .410 over-and-under - 1 Table 1

shotgun. The Marlin factory will also fur nish on order 278 Bee or .22 Hornet barrels in combination with the .410 bore and either of these can also be fitted with an extra set of .410 bore, 26-inch barrels.

Start of a "doughnutless" pattern

TRICKS BY

REFLECTION

ROM the simple reflection in a mirror or body of water, to the many and waried surfaces in which an object in reflected by the familiar "agency of light," photographs by reflection have been a popular pastime for a long time. Their popularity never pales because of the great variety of effects that may be obtained. There is no great that may be obtained. There is no great that may be obtained. There is no great manually problem to surround, but there are frequent instances in the work of anaetters where a better understanding and appreciation of reflection photography would have improved the result.

At the moment, we can think of five principal things that should be taken into account in producing good reflection piotures. These are as follows:

Figure 1

 The light used should illuminate the subject and be shielded from the reflecting surface itself as much as possible, for wherever the light strikes the surface the subject reflection is partially or totally lost.
 In focusing for the reflected image, the focal point is not the face of the reflection of the reflection of the re-

subject resection is parallely for totally join.

2. In focusing for the reflected image, the focal point is not the face of the reflecting surface, but twice the distance from the position of the subject to the reflecting surface. However, this will obtain only from the point of view of the subject. That is, it would be true if the engane were placed alongside the subject or at some point to the left or right of the subject, on a plane with the latter, equally deleast from the left or right of the subject, on a plane with the latter, equally deleast from the cases, the more practical way to put it is to say that the polat of focus is the distance from the subject to the reflection is to deleast the polat of focus in the distance from the distance from the surface plane the distance from the surface.

Figure 2

3. The angle of the camera should be such as to make the most of the reflection, which is the chief reason for the picture. This may sound like unnecessary advice because reemingly so obvious but a glance at some reflection picture efforts will show how frequently these pictures show the reflection in a position of minor emphasis.

4. Adequate exposure for the reflection, depending on the reflecting capacity of the particular surface used, is another point to watch. An exposure that will be correct for the subject itself under a given intensity of light will not always be right for the reflection. A mirror or calm body of water will give off the brightest reflections, practice.

Piguto 3

Figure 4

Figure 5

tically equal to that of the subject direct. A less efficient reflector may take twice as much exposure or more.

5. What cannot be accomplished com 5. What cannot be accomplished completely by point 3 in the matter of properly composing the reflection picture should be done in the printing or enlarging through "framing" or masking. More than is desired way be included in the picture because of the food length of the lens or because of an enforced diseases from the subject exciton. The property of the property

trick effect is an ordinarily straight resoci-ing surface—mirror. A celling compris-ing a member of separate mirrors joined togather "hreaks" sand duplicates subjects "sharewer the inter appear at the mirror joine. The stiple "straw"-like units are tubular lenge. At night an ordinary window will serve as

a reflecting surface almost as efficient as a mirror. Witness Figure 3, in which a desk and chair, even the door of the room, are faithfully reflected in the window, through taithinity renected in the window, into also may be seen the lighted windows in buildings in the distance. Inclusion of the window helps to clarify the picture.

A curious trick effect is shown in Figure

4, which was photographed through a window facing the street at the other end of an empty store. The late afternoon sun coming from the direction of the window shown in the picture illuminated the buildings reflected in the left third of the picture.

Figure 5 is an example of distortion by

reflection and foreshortening, or close view-point. The reflecting medium is an aluminum surfaced coffee pot. The odd vertical reflection is the face of the subject, which was reflected upright from the convex part of the pot and inverted from the concave upper portion.

DOUBLE-DUTY

FILTERS

PERSONS who own both a Contax and a Super Ikonta B are advised that a threaded adapter ring is available for the latter camera which will take the same filters as those used on the Contax, as well as the lens shade. Thus, the filters purchased for the Contax will serve for the other camera as well, eliminating the nesity of purchasing a separate set of filters for each of the two cameras.

GROUND LEVEL VIEWPOINT

ONE of the most frequently heard taboos is the one that advises never to have the camera face the subject head-on because such a pose is bound to lack interest. However, like other rules and regulations mete out to photographic workers, this one may sometimes he broken with impunity. Here NO OTHER MINIATURE CAMERA OFFERS SUCH VALUE!

THE NEW BABY BESSA JR.

One \$125 LONGINES One FEDERAL

No. 128 Enlarger Watch* (List price \$17.95)

Five Honorable Mention Awards, each consisting of a one-year subscription to Scientific American Remamber that these prises are to be given in each division—or a total of six watches and six enlargers plus 15 subscriptions to Scientific American, totaling \$1.327.35 in value

First Prize watches are standard men's pocket models, flecond Prize winners may choose pocket style or gualle-man's or lady's wrist watch.

Submit Pictures in ANY or ALL Three Divisions:

Division 1. Human—including portraits and other camera studies of people.

Division 2. Landscapes—including all scenic views, close-ups of parts of landscapes, seescapes, and so on Division 3. Action—including all types of photography in which action is the predominating feature

In each division there will be prizes of two Longines watches—"The World's Most Konored Watch"—and two Federal Enlargers as well as five Honorable Mention

This Contest Closes Dec. 1, 1939-All Entries Must Then Be in Hands of Judges

Address All Entries to

PHOTOGRAPHY CONTEST EDITOR SCIENTIFIC AMERICAN 24 W. 40th St., New York City

THE JUDGES: McClelland Barcley, artist Ivan Dmitri, artist and photograp Robert Yarnali Richie, commercial photograph is one that we believe does so successfully. Taken on the beach in mid-afternoon, the cameraman crouched on his tummy to face the subject eye to eye and shot away just as a fortuitous breeze waved the towel revealingly out of the way. The arrangement of the towel around the subject's head, the

From ground level

revelation of only one shoulder, the highlight on one side of the face, the waving hair, the pose of the subject's left hand and the curious smile, each lends its bit towards the whole. Unfortunately, the right hand, holding the lighted cigarette, is out of focus owing to too near a camera viewpoint and the wide diaphragm opening necessitated by the fact that the subject was in shadow

PRIZE CHANGE

DUE to war time conditions in Europe. and uncertainty as to shipping schedules, we are forced to make a change in the First Prizes offered in our Fourth Annual Photography Contest. As originally an-nounced, First Prize Winners would make their own selections of watch styles from the line of \$250 "Lifetime" Longines watches. Now, however, this must be changed and as conditions stand at present, First Prize Winners will be presented with \$250 "Lifetime" watches in the pocket style. Second Prize conditions have not been changed.

SATURATED SOLUTION

OCCASIONALLY the beginner comes tion," and wonders about its meaning. In preparing a saturated solution, a sufficient amount of the chemical is poured into a quantity of water so that some of the chemical is left undissolved. In other words, pour in a little more chemical than a given quantity of water will dissolve. The amount of chemical required will vary with the temperature—the warmer the water the more chemical will be needed; the colder,

Synchro-Flash

DESPITE the growing popularity of synchro-flash photography, in which snapshots in daylight are made with a flash gun, the photographer employing this means frequently is questioned as to the reason for using a flash when there is available

By synchro-flash

such a largess of daylight. Such was our experience one day as we were synchroflashing an outdoor game. In order to get a good ione in the sky, we employed an orange filter. The picture was made as the player struck the ball with his fist. The use of the flash helped to balance the light between the shadow areas and the sunlight. We expect shortly to present an article on the general subject of synchro-flash pho-

DUSTLESS TANK

REELS

THE popular Bakelite developing tank reels sometimes give trouble by collecting small dust specks within the grooves, thus causing undeveloped spots on the film. As the reel is revolved in the tank the dust is loosened and makes its way to the surface of the developing film and blocks development wherever it lands. One way of avoiding this is to give the loaded film a preliminary rinsing in water. But, of course, the best thing is to remove the offending dust and specks altogether. Drying the reels in a dust-free place is the way to do it. As soon as they have dried, they should be immedi-ately put away in a closet or drawer.

External appearance similar to Summar 50mm lens, except that diameter of front element is much greater New type optical glass used for front element, protecting lens aurface against adverse climatic conditions. Special collapsible supshade available for Summitar as are the Leux filters, in screw-in mounts.

LAFAYETTE HOME-MOVIE SCREEN: Crystal beaded screen reflecting four times light of ordinary diffusing screen over angle of 25 degrees. Wood frame also serves as base. Screen 30 inches high by 40 inches wide supported by metal post. Said to be free from halation, both in front and from sides. Weighs approximately six pounds.

MUNDER COLOR-FLASH LAMPS (30 cents each): For use with any daylight type film or plate indoors or outdoors Designed to produce illumination that has same color characteristics as bright sunlight. Also may be used with any tungsten or Photoflood type film. Munder No. 20B, 21 milliseconds to peak of flash; flash duration, 1/25 of a second; voltage required, 11/2 to 125 A. C. or D. C.; all lamps safety-coated.

LAFAYETTE "IN-SLIP" MOUNTS: Available in 22 sizes. Types for both horizontal and vertical prints. Openings vary from 3 1/8 by 3 3/4 inches to 10 1/2 by 13 1/2 inches, meeting needs for all standard size prints up to 11 by 14 inches. Mounts are of choice white antique finished material. Traced margin around window opening provides decoration. Another series especially intended for exhibition prints free from decorations of any kind, available for vertical and horizontal mounting of 8 by 10 and 11 by 14 inch prints.

ARGUS MODEL M CAMERA (\$7.50) · Takes single or double frame pictures, twelve 1 by 11/2 double frames or 24 single frames. Equipped to work as close as 24 inches. Shutter marked "dull," "cloudy," "bright," "sunshine," or "color." Triplet Anastigmat 1/63 color corrected. Uses specially spooled Dufaycolor film and new 35mm Arguspan film.

F-R "Special" Adjustable Roll Film TANK (\$1.85; double flange, 50 cents extra): Made of Bakehte, with stainless

. steel parts. Adjustable to all popular complete 36-exposure 35mm roll up to and including 116. Film may be loaded into

reel from either inside or outside (or both when loading more than one roll). Because of inside loading feature, films may be developed in rapid auccession irrespective of how wet reel may be. Only eight ounces of solution necessary for 35mm roll; total capacity of tank 16 ounces for largest size film. Revolving light trap stops light from entering funnel and aids quick filling and distribution of solution over film. F-R patented check stop prevents film unrolling during agitation. Double flange permits de-veloping two full length rolls of 35mm. Knurled agitating ring built onto reel; permits thermometer to be used during deve ment and aritation.

BOOKS r

Amateur Photographers

New WAYS IN PHOTOGRAPHY, by Jacob Deschin. Eminently practical from every point of view, this new book contains nothing of theory and nothing that the advanced amateur photographer will not find valuable photographer will not find valuable in one way or another. It covers the whole range of ametur photography, discussing such things as trick pho-tography, photomurals, retouching, infra-red, and a number of other sub-divisions that will not be found else-where in as clear and concise a man-

SO YOU WANT TO TAKE BETTER PICTURES, by A. P. Peck. A friendly, face to-jace chait with the camera owner who has his developing and printing done at the photo shops, yet wants to know enough about his camera and its uses to enable him intelligently to utilize it to best denniage. Over 200 pages, dozens of illustrations, \$2.10.

Universal Photo Almanac and Mar-UNIVERSAL PHOTO ALMANACAND MARKET GUIDE. How, when and what to photograph in order to make money with your camera; where to sell different types of prints. \$1.00.

AMATEUR FILM MAKING, by George H. Sewell, A.R.P.S. Useful to the beginner as well as the expert movie maker. Tells about films, cameras, exposure, film editing, story telling with the famera, and so on. Illustrated, 31.60.

CHAMPLIN ON FINE GRAIN, by Harry Champlin. A complete hand-book on the entire subject of fine grain, in-cluding formulas and how to com-pound and use them. \$1.85.

HOTOGRAPHIC HINTS AND GARGETS. by Fraprie and Jordan. How to make all kinds of photographic accessories: from film clips to cameras to ligh ing equipment, and so on; 250 article and nearly 500 illustrations. \$3.60.

PORTRAIT PHOTOGRAPHY, by H. Wil-liams. Fundamental principles of composition and lighting, paving the way to satisfactory results in this particular branch of photography, \$4.35.

PHOTOGRAPHIC ENLARGING, by Frank-PHOTOGRAPHIC ENLARCING, by Frankwin I. Jordan, F. R. P. S. One of the
most interesting and authentic books
on enlarging. Its 224 pages cover
every phase of the subject and 75
illustrations, many of them salonsolnners, show the value of correct
technique, \$3.60.

SCIENTIFIC AMERICAN

24 West 40th Street New York City OOKS___

JACOB DESCHIN, conductor of our "Camera Angles" department, will answer in these columns questions of general interest to amateur photographers. If an answer is desired by mail, enclose a stamped, addressed envelope. Queries should be specific, but Mr. Deschin cannot undertake to draw comparisons between manufactured products nor to advise on the purchase of equipment or materials.-The Editor.

O. I have heard that the backs of negatives may be so treated as to permit working on them in order to modify the image. Will you please plain how this is done?—C. S. K.

A. Prepare the following formula: 18 grains Sandarac Mastic 4 grains200 minims Ether Benzol 80 to 100 minims This is spread evenly over the back of the When dried, the resulting matte negative. permits the application of chargoal or crayon for the purpose of intensifying details or masses, adding clouds, and so on. The fineness of the matte surface is determined by the amount of henzol used, the greater the amount, the finer the surface obtained.

- O. How long does it take for brown stains to appear on a print that has not had the hypo properly washed out of it?-F, L, D,
- A. No definite answer is possible, for it will depend on the amount of hypo left in the print and might take a few months, a few years, or longer. Of course, you know that various tests are available for determining whether a print has been washed free of hypo.
- Q. I have been trying to use my camera, which takes vest-pocket film, for copying the printed matter in books, magazines, and so on. Employing Mazda (not Photoflood) illumination and the standard orthochromatic and panchromatic films in the standard fine grain developers has proved unsatisfactory, the enlarged prints being grayish and muddy from lack of contrast even when a hard paper is used. Would you advise getting a 35mm camera so that I may use positive, process, and other films of a contrasty nature? Or would a contrast developer, such as D-11, on film such as Panatomie X prove sufficient-ly contrasty for crisp prints?—J. R. B.

A. For best results, showing clean-cut reproductions of the printed matter copied, positive film will be the most satisfactory. Development in the contrast developer D-11 at 65 degrees for five minutes, should prove

The fault has not been in your lighting,

which is probably satisfactory, provided it is evenly distributed over the surface to be copied, but in your choice of film. In this type of work not only do you have no need of the color sensitivity of orthochromatic and panenromatic films, but this actually is a deterrent to satisfactory work. You might try the suggestion contained in the last sentence of your letter and see if the resulting contrast is sufficient for your purposes, but positive roll film in a 35mm, camera, or positive cut-film in a larger camera, will do the job in the most efficient way.

O. Infra-red film with filter calls for 1/20 of a second at f/3.5. I have a Goerz Dagor f/6.8 lens. What will the exposure be for this lens at its widest opening?-M. S.

A If the exposure you cite for 1/35 opening is correct, the exposure at \$/6.8 will be four times as long, or, in this instance, 1/5th second.

Q. I have the opportunity of pur-chasing an old model camera, with a Tessar f/4.5 lens, which takes a sixexposure roll. The red window is in the middle center of the back. In examining the camera I find that the back acction of the lens has been removed. How good is this lens with the two front elements only? Could you tell me if the aix-exposure roll is easy to buy? I have the idea of using the 120 roll but I am not sure whether the numbers which indicate the exposures are marked all the way across the safety paper.-A. P.

A. The lens cannot be used as it stands because the Tessar is of the so-called nonsymmetrical type and therefore requires the use of all four elements which comprise the Tessar. The six-exposure roll is not now available in this country. By some experimentation, it is quite possible for you to work out a scheme whereby you could em-ploy the 120 or similar roll-film size. The number markings on the back of the safety paper now include three rows, the left for the 8-exposure style camera, the right for the 12-exposure camera and the center for so-called vest-pocket, 16-exposure cameras. For your particular camera, because the window is in the center, you will have to use the center row as the basis for working out your particular requirements.

THE Book Department of Scientific American is conducted, with the co-operation of the Editors, to make available for you as comprehensive book service. Each month the Editors select and review in available titles, including prices. When these columns are wooks in a vide inquiring about books, please be specific; remember that we can be of the greatest help only when you tell us just what you are looking for.

> A successful engineer himself, with a nationally known corporation, the volume is built on his wide experience and observations. In content, it runs from a chapter: "Eco-nomics and the Engineer," through the whole range of engineering and industrial whole range of engineering and industrial activities to a chapter entitled "The Engineer as a Citizen," and a further note on "Economic Studies." (463 pages, 6 by 9½ inches.)—\$4.10 postpaid.—F. D. M.

OF ANTS AND MEN By Caryl P. Haskins, Ph.D.

A STUDY of the life of ants, especially with regard to their similarities with another social animal-man. Not a light, popular work and probably best suited to readers having a little previous knowledge of ants. (244 pages, 6 by 9 inches, 15 il-lustrations)—\$2.85 postpaid.—A. G. I.

THE BOOK OF INDOOR HORRIES Ry Emanuele Streri

TERRARIUMS, window-box gardening, TERRARIUMS, window-box gardening, roof gardening, dish gardening, collect-ing cacti, aquariums, feathered pets, pottery ing cacti, aquariums, feathered pets, pottery making, leathercraft, plastics, pewtercraft, soap carving, chip carving, etching, and bookbinding—these are the indoor hobbies dealt with, chapter by chapter, in this book, about which one terrarium-aquarium-gar-dening hobbyist close to this reviewer says the treatment is practical and obviously prepared by an author who writes from his own pared by an author who writes from his own experience. It makes a big difference in a book whether this is the case. (430 pages, 6 by 9 inches, 196 illustrations.)—\$3.10 postpaid.—A. G. I.

MAN AGAINST MICROBE By Joseph W. Bigger, M.D.

IT would be difficult to write a more lucid, more directly revealing, popular yet scientific, account of the rudiments of bacteriology than this book which this reviewer read from beginning to end as a pleasure and not as a task. It tells what nicrobes are, how they are cultured, identimicrobes are, how they are cultured, identified (just enough insight into the intricacies to show the reader what it is that the mysterious bacteriologist does, without bog ging him down with details); also what microbes do and the main points about immunology—toxins, antitoxins and so on (again just enough to satisfy the reader who wishes a clear elementary understand-

or immunologist). It also tells the long story of man's conquest of microbes, and away os man s conquest et microbes, and it winds up with a lengthy discussion of practical applications of bacteriology in everyday life. A meaty work. (306 pages, 5 by 7% inches, 35 illustrations.)—\$2.60 postpaid.—A. G. I.

THE STORY OF SURGERY By Harvey Graham

UNDER the pseudonym of Harvey Graham, a prominent British physician Oraham, a prominent British physician has written this story of the long evolution of the art of surgery from early times to our own days. Almost throughout, the reader will shake his head and marvel at what men once thought was beneficial. The scope is best suggested by some of the chapter heads: Greek and Roman surgery; surgical remaissance; the black death; barber surrenaissance; the black death; barper sur-geons and chirurgeons; corpses, curiosities and quacks; a one-man revolution; sur-geons become gentlemen; the quacks and the brothers; John Hunter; struggle for corpses; death of pain; Lister; after Lister; today and tomorrow. The author knows how to tell good readable, absorbing narrative: a live book. (425 pages, 6 by 9 inches, 23 illustrations) -\$3.85 postpaid.-A. G. I.

WONDER PLANTS AND PLANT WONDERS

By A. Hyatt Verrill

ODITIES of the plant world—plant giants, intelligent plants, plants that sail seas, magic plants, plants with strange uses, plants that grow while you wait, and uses, plants that grow while you walt, and so on—is the central idea of this fascinat-ing book by a world traveler who has brought together within two covers practically all the legitimate wonderlore of plants. Many scientists are likely to balk at the chapter on intelligent plants, particu-larly the account of the tamed, pet, sensitive plant that apparently knew the author and trusted him so completely that it did not trusted him so completely that it did not bother to close its leaves in the usual de-fense—a "one-man" plant. (296 pages, 5½ by 8 inches, 71 illustrations.)—\$3.10 post-paid.—A. G. I.

SIMPLIFIED HOUSEHOLD MECHANICS

By A. Frederick Collins

COMETHING more than the usual "how to fix a leaky roof" book for the house-hold mechanic has been turned out by this note mechanic has been turned out of mis-prolifies writer of books for the handy man. In this latest of his products, he presents simplified explanations of how the mechani-cal and electrical equipment of the average home is made, how it works, and sensething of how it is kept in operatios. It enables

SCIENTIFIC AMERICAN 24 West 40th Street New York, N. Y.

ATOMS IN ACTION

By George Russell Harrison

APPLIED physics is the scope of this most readable volume by a professor of experimental physics and director of the research laboratory of physics at The Massa-chusetts Institute of Technology. Physics in agriculture; applications of the physics of sound; glass; electronics; radio; spectroscopy (this chapter appeared as pre-publication articles in the September and October numbers of Scientific American); physics in medicine, optics, television, music, air conditioning and aviation-these give the general scope. The treatment is the oppo-site of technical; your mother or sister could follow it easily to learn what these things are about-without being asked to learn too deeply. The author has a wide reputation as a facile expositor of applied science. (370 pages, 5½ by 8½ inches, 19 illustra-tions.)—\$3.60 postpaid.—A. G. I.

NEW PATHS IN PHOTOGRAPHY By Andreas Feininger

"OFF the beaten path" may be a trite expression but it surely applies specifically to this newest book on creative photography. The author first discusses various phases of photographic operation and processing, an understanding of which is necessary for an appreciation of the 47 full-page plates which follow. With this book as a guide, or as an inspirational source, the photographer will find the way open to unusual camera effects. (10½ by 11½ inches, 15 pages of text, and 47 plates.)—\$2.85 postpaid.—A. P. P.

APPLIED ECONOMICS FOR ENCINEERS

By Bernard Lester

819

E XECUTIVES in industry have repeatedly pointed out that the technical graduate is handicapped by a lack of training in the practical principles of economics. The author of this book believes that the economic theories now prescribed for students are not applicable to present conditions in a practical way; hence this volume. In it, Mr. Lester has attempted to give (successfully, we believe) the sort of discussion which would quickly acquaint the technical man with the principal prob-lems and human relations he should know if he is to conduct a business and

FOR OTHER BOOKS YOU WANT, SEE PAGES 292 AND 310

the reader to understand more thoroughly the fundamentals of household equipment before he attempts to make repairs. (318 pages, 5 1/2 by 7 3/4 inches, well illustrated with drawings.)—\$2.60 postpaid—A. P. P.

ELEMENTS OF ORDNANCE

Prepared under the direction of Lt. Col. Thomas J. Hayes

IT would be impossible to give an adequate idea of the scope of this volume in this limited space. It is sufficient to state that the volume is a textbook for the use of cadets of the United States Military Academy and that it covers completely the questions of all ordnance manufacture from the smelting and refining of metals, construction of guns, the chemistry of explosives used, the types and uses of artillery, to the mathematics of ballistics. Projectiles, fuses, bombs, grenades, rifles, automatic and semi-automatic weapons, armor, tanks, and combat vehicles are also discussed, (715 pages, 6 by 9½ inches, numerous illustrations.) —\$6.60 postpaid.—F, D. M.

SCIENTISTS ARE HUMAN

By David Lindsay Watson

E VEN the scientist himself finds it def-ficult to think straight—logically, unemotionally-and this book is a fundamental critique of modern science, though it makes considerable demand on the reader's background. (249 pages, 5 by 7 3/4 inches.) -\$2.35 postpaid.-A. G. I.

INDUSTRIAL SOLVENTS Ry Ibert Mellan

IT would be difficult to over-estimate the I importance of solvents as there is hardly an industry in which they are not used to some extent. This comprehensive volume starts with theories of solution, discusses all the aspects of industrial solvents, and ends with a chapter on graphical expression and interpretation. (480 pages, 6 by 9 inches, illustrated, 267 graphs, 126 tables of properties.) -\$11.10 postpaid.-L. B. P.

THE SOCIAL FUNCTION OF SCIENCE By J. D. Bernal, University of London

AN examination, detailed and thought-provoking, of the unfortunate fact recently becoming more and more evident that science can be used not alone for man's good but destructively, as in war, and wastefully, as in inefficient institutions and methods of research; with recommendations regarding what could be done about it. (482 pages, 5½ by 8½ inches.)—\$3.60 post-paid.—4. G. I.

THE LIVING THOUGHTS OF DARWIN Presented by Julian Huxley, M.A., D.Sc., F. R. S., assisted by James Fisher, B.A.

Drikwin's own writings make alow, discussion of the subors here therefore height this small book of carefully chosen anospits from them, and tied them together with ramaing pertinent comment. Thus the reader will be in first-band touch with Dawkin, see without point through a year or use of slow plotding through a line withing will go with the such subhance. Util papels, 4% by 7 laches, con illustration—48.84 apages, 46.85 or 10.85

TELESCOPTICS

A Monthly Department for the Amateur Telescope Maker

Conducted by ALBERT G. INGALLS

N OW that the amateur telescope making hobby has thrived for a dozen years since this magazine gave it wide scope, there are numerous amateurs who can down to froressional grade—sometimes even better, since the amateur, unlike the professional, can afford to put an unlimited

Figure 1: Holcomb's heavy mounting

amount of time on an optical surface until it is as nearly perfect as any optical surface concernment. In few communities such concernments, the few communities such cluded or are concluding arrangements with local educational institutions—hip almost colleges, universities—to make and institution concernments, the educational institution concernments the few discussions of the few motified advantage. For example, the educational institution concernments the for the observatory. The amateurs put in the skill and the elbow grease. The finished observatory is then available to both coften also; to local townsment).

totten, also, to local townsmen).
The 12" reflecting telescope shown in Figure 1 was made by an amateur, J. M. Holcomb, 40 Clarke St., Burlington, Vt., for St. Michaels College in Burlington's suburb, Wincoakl. Asked to describe it, Holcomb states.

"The mounting is compact and rigid, operates smoothly, and is convenient to use. The setting circles are divided to half dogrees and are illuminated. The driving clock (Figure 2) is run hy a synchronous motor and is adjusted to sidereal time. The mounting is also provided with also motion controls, that in declination heng manual, that in right ascension motor driven.

"The building (Figure 3) consists of a 12 by 26' classroom on ground level and a wooden-framed, metal-sheathed dome 12' in diameter, 9' high, above. The telescope rests on a ten-ton reinforced concrete pier entirely free from the building, in order that no vibrations may be transmitted to the telescope

"I believe the unit can be termed an amateur job, despite the fact that I did not actually lay the bricks, mux the concrete, or pour the iron castings for the mounting. I did design it all, also made the patterns, supervised the masonry, and did the rest of the construction.

"The mounting contains a temporary 8" mirror made by Father A. Rivard, S.S.E. of St. Micbaels College, but a 12" mirror is being made."

The rugged proportions of Holcomb's

mounting design are worth close study. This telescope will not shave, as many do, when a fly alights on it. A telescope mag-nifes its own whatians just in the measure that it magnifies the stars, hence whatians that remain wholly invashle to the direct look cause the stars to dance wildly to the look through the telescope. This is why ordinary enters for rapidity in machines, supports, and so on, are much tow weak for telescope mounting design. A telescope mounting design.

INITH in a long line of sight Noutons una rangeng from 4" to 12½", and from 1/5 to 1/18, and hull over a period of four years, a shown in Figure 4, with its maker and owner, John J. Stoy, 450 Hutt Bulding, Atlania, Ga. In his letter Stoy styles himself "Director of the Smoky Holow Freshar Observatory," The telescope is a 12½" of 1/8, and the total weight of elescope and piers is 3550 pounds. The design is conventional but unusually clean. The polar aris counterveight, 'Stoy writes, "is open to argument as to necessity, but it brings the center of mass to the center of the pier." This last idea seems excellent, and in keeping with principles of mounting design started by Porter in the treatise "Amandia Ratery Making," fourth edition.

Figure 2: The electric drive

Close inspection of the figure will reveal a very smooth, clean declination ans caring and union for tube attachment. These were cast in fron, from patterns made and donated by Fred Ferson, Blozi, Miss, author of the chapter on modifing and casting, in "ATMA," and a friend of Stoy's. The upper end of the tube rotates. The tube is venulated through an oversized cell with 9-point auspension.

How well your scribe realls the day when Stoy received and began working the 12½" Pyrex disk for this telescope, which, it seems, was past as bit hubbly Daily thereafter the mails brought generous samples of the most competent old-fashioned southern cussin', but finally Stoy learned to defeat the bubbles and the profassity imperceptibly dwindled until, at last, he actually came around almost to loving Pyrex. Even now, however, you must smile when you sy "hubbles" within his hearing. (It is impossible to cast Pyrex disks without some bubbles—can't pat is the enough and fluid enough, because of its high melting point, for all the bubble to rise—but the makers throw out the poer clishes. Stop also before used his mirror touce after most of the world would be the called it a day—we asspect would be the called it a day—we asspect would be the called it in the called it is a day—we asspect would be the called it in the called it is a day—we asspect would be the called it in the called it is a day—we asspect would be the called it is a day—we also show that the called it is a day—we have a day of the called it is a day of the called i

THE following communication is from James G. Baker, of the Harvard College Observatory:

"In reading through the very interesting article by Hendrax and Christie in the August Scientific American the present writer has noticed some incompleteness that might cause amhituous amateurs a bit of graft. All the various types presented by the authors are certainly workable, but caution must be exercised in order that cameras constructed should not exceed in aperture that which is justifiable theoretically.

"The thick mirror type discussed (Figure 3, IX in the August article) is optically inferior to both the ordinary and the solid kinds of Schmidt camera, although still quite a good camera in Itself. The authors have failed to point out that the position of the apparent center on the axis depends upon the angle that the incoming rays make with the optical axis, and that this type of camera does not possess the symmetry of the Schmidt arrangement. Just as in the case of the usual Schmidt the third order errors are zero, which fact insures good performance, hut, optically speaking, the thick mirror is not aplanatic he the third order, whereas the Schmidt is aplanatic to all orders of accuracy. The practical effect of this lack of perfection is to limit the speed and usable field of the caniera, as compared with the Schmidt in glass. By a suitable deformation of spherical mirror and intermediate refracting surcas minor and intermediate retracting sur-face, one can obtain nearly Schmidt per-formance, but the required optical work is more involved. The Zeiss company has re-cently produced a thick mirror system involving only spherical surfaces that has a flat field. The authors of the August article have neglected to point out that, as in the case of the usual Schmidt, the thick mirror type has a curved focal surface, spherical and concentric with the spherical mirror

Figure 3: Observatory, St. Michaels

Figure 4: Stoy and his "Bessie"

face and should be made so. The authors state on page 119 that the speed of an //0.66 camera can be obtained with the field and correction plate curvature of an //1 of the usual kind, but this is not correct. The depth of the correcting surface is exactly n times deeper, zone for zone, than for the usual Schmidt of the same physical size, and the usable field about a times larger, angularly, in the case of the solid schmidt, and about the same in the case of the thick mirror system, all compared with the usual Schmidt. The letter n used above stands for the index of refraction of the glass of the thick mirror. The index of refraction that sppears in the denominator of the expressions for the correcting surface will be that for the glass of the correcting plate, in the above thick mirror system.

"The performance of the Schmidt in glass is truly remarkable. The solid glass combination was discovered independently and was investigated through its fifth order image errors in May, 1938, by the present writer, and discussed at the October, 1938, meeting of the Optical Society of America. The solid Schmidt, I have heard indirectly from Bergedorf Bergedorf Observatory, in Germany, where Schmidt worked,-Ed] workers, was contemplated by Schmidt himself, some years ago. Sinclair Smith seems to have been the successor to Schmidt in coming upon the solid Schmidt, but the pubheation was delayed by his untimely death fortunately concluded that the thick mirror type constitutes the only practical way of getting to the focal surface, as Hendrix did also in the early stages of his work. Hendrix, however, has now provided an intype. An off-axis type provides another.

"Let us compare the solid Schmidt with the ordinary Schmidt of the same physical size, that is, with the same aperture and radius of the mirror surface. The focal length is 1/n that of the usual Schmidt, the people of greater, the depth of the correcting people of greater, the depth of the correcting matic aberration disk a times smaller as each wavelength, and the curvature of the field the same. The third order sulgmatism, resistance of the same that the theory of the correcting plate, is alightly smaller than that for the usual Schmidt, and for both is numerically of the fifth order. The first the ordinary schmidt is the variation of spherical aberration with angle. This detect is several times smaller for the solid Schmidt shap, for the usual kind. The

THE BUILDINGS COUNTR

IF you are tempted to jump from your first 6" telescope making job to a much larger size, the accompanying photographs and description by a worker who jumped

the other way and put his energies into refinement may be worth considering. It is a 4" made by L. J. Ashby, 437 Stone St., Kalamazoo, Mich., and by Mrs. Ashby, and is equal in both design and finish to profesis equal in both design and mining to profes-sional work. Both, we say, since we have seen a few telescopes with very exquisite or even over-elaborated finish but poor de-sign. Ashby, who has been a telescope maker for several years, writes:

"There are a few who want a really porta-ble instrument—one which does not require several strong backs and a truck to handle and transport. My wife cannot conveniently carry around even a 6", hence this 4" Newcarry around even a 6°, hence this 4° New-tonian which carrise easily in the family car and can be handled by a woman. Some details are: Mirror made by Mrs. Ashby, with much oral but no manual assistance on my part. No scratches. Tripod, wood. Set-ting circles, graduated 5 minutes and 2°. Slow motions in both directions—in R.A.

lined for better temperature performance. Rack and pinion focusing. Level and com-pass for quickly aliming polar axis. Finder, diagonal type, 7X, 5° field. Eyespicoce, 1°, '4', '4' (after Clarke, in 'ATMA.). Fladd of view with 1" cycpicoe, 1½'. Tube wt.,

111/2 lbs., mount and counterweight, 27 lbs. Cost, \$35. Time, 210 hours.

"This little telescope resolu of Epsilon Lyrae with '%" eyepiece, Pr

After all, no beginner on his maiden teles-cope should attempt so fine a job as the Ashbys' but should aim to equal its design Ashbys' but should aim to equal its design for rigidity, especially at two vital places: on the declination axis near the tube, where a large cross-section is here seen, and in the plate between this axis and the tube, which is here amply thick.

A little telescope, but built like a watch.

ANOTHER TN (which stands for Teles-cope Gnut, socially correct designa-tion for telescope makers.) who, after making the beginner's 6", did not seem to drop to a 4" because of its portability, is G. F. Hofferberth, R. F. D. 3, Dayton, Ohio, a rionerberin, R. F. D. 3, Dayton, Unio, a telescope maker of long standing and now owner of a 12" Cassegrainian. It has a tube of copper sheet which was rolled, the edges scarfed and silver-soldered. The finish ("engine finish") was done on a drill press with a rubber grommet, oil and emery. Hof-ferberth made the patterns and did the ferbeth made the patterns and the imachining for the polar axis support and bearing and for the well-proportioned fork, but the very beginner—the absolute tyro need not worry about such refinements as the latter, since easier methods are available.

TELESCOPTICS

(Continued from preceding page)

are all zero with exception of spherical aberration, as in the case of the usual Schmidt. The front surface of the solid Schmidt. The front surface of the solid Schmidt behaves as saingle prime face, so that, for large field angles, a star photo-graphs as very short spectrum. This defect is of no importance in spectroscopy, for which such a glass camera is most useful. The Harrard Observatory has under con-traction a solid off-sair Schmidt, for which the focal ratio has been pushed to the ex-treme of 1/0.30. The focal length is ISmm, and the tushle field smil linearly, or about 12 decrees. The field is still larger for re-12 degrees. The field is still larger for re-

duced aperture.

"A variation of the Schmidt in glass is offered by converting the apherical mirror.

into a spherical lens surface, with a cor into a spherical lens surface, with a corre-sponding change in the depth of the correc-ing surface. Because of the small power of a lens surface of the same radius as a mirror surface, as compared with that mirror, the aperture-ratio of this type camera is limited to 1/1.5 or allows. It is, nevertheless, a true Schmidt camera. The focal surface is spheri-cal and conceptic with the large surface.

Schmidt camera. The food surface is spherical and concentrie with the lass surface.

"In the article by Hendrix and Christic even for the folded type, they mention a plane food surfaces to be made occurs it among the correspines surfaces to be made to the tendency of the control of the cont

gether the complete story. The Wright type, in addition to having double the chromatic trouble of the Schmidt of the same focal length and aperture, has astignation of the third order, that seriously limits the field at high apertures. As the authors state, cameras of //3 and //4 are satisfactory for limited fields, but then there is no need to make one in glass. For spectrographic purmake one in glass. For spectrographic pur-poses, the Wright type, called apocifically the "short" type to distinguish it as one of a family presented by Wright, also has a curved field, and on that surface third order satigmatism along the apectrum is zero.

The present writer would like to caution the amateur, who is contemplating a very the amateur, who is contemplating a very iast camera, to compute his correcting aur-face from the more accurate formulas given by Wright in 'ATMA,' and to try contacting some person who has made a Schmidt to rheck the computation. If the amateur makes a solid Schmidt, he should use the ordinary formulas for a correcting surface, but with a factor of n, the index of refraction, throughout, so that the correcting plate is n times deeper, zone for zone, than is the case for the usual Schmidt. Moreover, the position of the focal surface must be carefully computed.

"Hendrix and Christie mention that the essest form of correcting plate to make is one for which center and edge are at the same height; that certainly must be correct from their wealth of experience and practice, but I would like to point out that the departure from the nearest sphere (one through center and edge) is nearly independent of their parameter k and, therefore, that the amount of aspherical figuring is

"The above is in friendly criticism, with sn eve toward aid to the amateur, and in no way should detract from the excellence and usefulness of the article as a whole."

In his letter of transmittal, Baker states that he has the entire set of quantitative formulas that bear on the Hendrix and Christie designs and will be willing to cooperate with any amateur desiring information, who is really serious about making some of these telescopes. In each case, he states, the many factors should be carefully balanced before the maker starts pre-cipitously on a part not justifiable theo-retically. He will give information to anyone wishing to know about the performance of a Schmidt of given specifications, or will recommend specifications to fit a given need.
He has also designed a family of flat-field cameras, equivalent in performance to the Schmidt camera, which he described before the American Astronomical Society last summer

Priority on (1) the fact that the correcting lens of a Schmidt should be made larger than needed and masked out, to facilitate the work, (2) the use of a liquid on the correcting lens while it is ground to shape, also use of a pattern of straight lines at the also use of a pattern of atraigm mass e-plate holder, and (3) the interpretation of the zones by the method just described, all described in the Hendrix and Christie article of last August, is claimed by Arthur De Vany, 727 Sylvan Court, Davenport, lows. In letters offered this department for lows. In letters offered this department on publication long ago, De Vany described these methods. Owing to your scribe's pro-crastination in publishing them they were offered to Reputer Astronomy, which published them a year or so ago, and it is now desired to mention the matter in order as

TRADE MARKS

AND
UNFAIR
COMPETITION

By ORSON D. MUNN

A TRADE MARK is an intangible asset of a business, yet its actual value may grow so large that it becomes the very foundation on which depends the whole structure of the business. Because of this fact, every business man should have available such information on trade marks as will enable him to judge with a fair degree of accuracy the desirability of any mark which he may be considering.

Here, in one handy volume, written in non-legal terms, is a simple yet comprehensive interpretation of the Federal statutes and the body of common law relating to trade marks and unfair competition.

PATENT CHANGES

THE changes made in the Patent Law THE changes made in the during the last session of Congress were designed primarily to shorten the period between the completion of an invention and the issuance of a patent covering the invention. The most important change in the law relates to the very important twoyear period. Heretofore a patent application could be filed within two years of the first publication of an invention or within two years after an article embodying the invention was placed on sale or went into public use. Under the amendment to the law the period of two years is reduced to one year after August 5, 1940.

Another amendment which is corollary to the above amendment and which goes into effect on the same date relates to th practice of copying claims from issued patents for interference purposes. Ileretofore a person claiming to be the inventor of certain subject matter covered by an issued patent could copy the claims of the issued patent within two years of the date thereof. This period has now been reduced

Another important change, which became effective on October 5, 1939, relates to the simplification of interference practice. An interference is a proceeding before the Patent Office between two or more claimants for patents on the same subject matter to determine which claimant is the prior inventor. Interference proceedings are necessarrly involved and frequently consume a reat deal of time through no fault of the Patent Office, with the result that the issuance of the patents involved is delayed. Prior to the change in the law, interference edings were heard in the first instance by an Examiner of Interference. An appeal could be taken from his decision to the Board of Appeals of the Patent Office and an appeal could be taken from the decision of the Board of Appeals to the Court of Customs and Patent Appeals or in the alternative a suit in equity could be filed to compel the issuance of a patent. The intermediate appeal to the Board of Appeals has now been eliminated and the interference is heard in the first instance by a board of three Examiners of Interference rather than a single Examiner of Interferences.

A fourth amendment to the law empowers the Commissioner to require a responsive amendment to be filed in connection with pending patent applications in a shorter time than the six months previously allowed by the law but under no circumstances in

A fifth amendment abolishes so-called re-newal applications. Heretofore upon the allowance of a patent application the appli-

cant had six months within which to pay the final government fee. If he failed to pay the fee within that period the application became forfeited subject to being renewed in an additional six months period upon the payment of another government fee. The original intention of the renewal provision of the Patent Law was to permit a poor inventor who could not afford to pay the final government fee an additional period of time within which to obtain the necessary funds. However, it has frequently been charged that the renewal provision of the statute was utilized by wealthy companies and individuals to delay the issua of a patent and thereby prolong the effective period of the monopoly. The renewal provision has now been abolished and the Commissioner of Patents now has the discre tion to receive the final government fee if paid within one year after the expiration of the six months period allowed for the payment thereof.

The sixth amendment to the patent law is intended to increase procedural efficiency and provides for transferring jurisdiction over the registration of copyrights on com-mercial prints and labels from the Commissioner of Patents to the Register of Copyrights. The provisions of this amendment become effective on July 1, 1940.

ALUMINUM

FROM time to time rumors have been resulting from the use of aluminum cooking utensils. It is interesting to note that the Federal Trade Commission has taken cognizance of these rumors and has filed a complaint against the publisher of pamphlets dealing with this subject, charging that the representations contained in the pamphiet deceive the publi-

The titles of the pamphlets involved are "Poisons Formed by Aluminum Cooking Utensiis" and "Are You Heading For The Last Round Up?" According to the Commission the pamphlets contained such state having seventeen carbuncles, threw out his fancy aluminum ware. The carbuncles dis-appeared"; also "Another fed his dog from an aluminum dish; the dog died from cancer of the face."

JOINT OWNERSHIP

THE weakness inherent in the joint ownership of a patent is illustrated by a recent suit for patent infringement. The suit was brought by the co-owners of a patent for a non-refulable drum for lubricating oil against a prominent oil refining company. The Court found that one of

the co-owners of the patent had previously entered into a contract with the oil refining company wherein he had granted a licens to the company to use the invention covered by the patent. The usual rule of law applic able in such cases is that a good and valid license may be granted by one of the coowners of a patent and thereafter the licensee is not liable to pay damages or profits for patent infringement to the other

In the case in question it was argued by the co-owners that a different situation existed because of a contract between the co-owners whereby each agreed not to dispose of his share in the invention without the written consent of the other. This agreement it was contended rendered it impossible for either of the co-owners to grant a license without the consent of the other. The Court concluded that while the agreement was no doubt binding between the parties it was not binding on the oil refining company in the absence of notice of the agreement. The Court found that as a matter of fact the oil refining company did not have such notice and that accordingly it was licensed to practice the invention covered by the patent.

GOLD MEDAL.

THE Commissioner of Patents has ruled that the words "Gold Medal" are not descriptive of various items of merchandise or of their characteristics or qualities.

This rule was handed down in connection with the application for the registration of the words "Eventually Gold Medal" as a trade mark for poultry, dog, and cat food The Examiner rejected the application of the grounds that the words "Gold Medal" were "descriptive of various items of merchandise that have competed successfully in expositions or contests and awarded gold medals."

An appeal was taken to the Commissioner of Patents who reversed the decision of the Examiner, holding that the words "Gold Medal" were merely suggestive of the characteristics of the merchandise and not descriptive thereof.

FOREIGN COMMERCE

THE Federal Trade Commission has recently shown an interest in unfair methods of competition in foreign com-merce. Thus, it has issued a complaint against an importing and exporting company charging that the company had in duced a Japanese manufacturer to misbrand Japanese-made optical lenses and fulsely t mark them "Made in U. S. A." The company is also charged with procuring foreign business by "negotiating the export of such falsely branded products to Cuban importers.

The Commission alleges that purchasers in certain foreign countries, including Cuha, have a preference for products made in the United States as distinguished from like products made in Japan, and that these countries grant reductions in import and custom duties on products made in and imperted from the United States. Under the circumstances the Commission charges that the company's practices are unfair and react to the prejudice of competitors and to the prejudice and injury of United States manufacturers of optical lenses.

How to get rid of an

INFERIORITY COMPLEX

A true story of a man who found that self-confidence is not a matter of education or luck

HE WAS GOOD in his job No one denied that But he felt inferior to his associates Most of them were college men He envied them the mysteriousthingcalled "background"

Today he happens to be one of the principals of the business. But more important, he has lost his inferiority complex Instead of envying his once better informed associates he is their equal.

His case is by no means unusual He has learned the secret that the reading of great literature opens the gateway of the mind and offers a broader view of life This broader view inspires self-confidence. In a word, it's sulture.

There are thousands of men today who lack the essential background who necessary for success in every field of life and who don't know where to turn for it. The cold stone front of a public library suggests groping among thousands of books. "What are the really great books?" you ask.

DR. ELIOT'S FIVE-FOOT SHELF OF BOOKS

THE HARVARD CLASSICS

The question has been wonderfully answered by America's greatest educator, Dr Eliot, forty years president of Harvard. He made it a vital part of his great life work to assemble in one set the really worthwhile writings. These books place you on an equal footing with the best educated of your associates.

LIBERAL EDUCATION AT YOUR FINGERTIPS

This supreme library of 418 immortal masterpieces is unified into a living, powerful educational force by the marvelous working index containing 76,000 entries, guiding the reader to an understanding of world culture

The Harvard Classics is now offered at the lowest price in its history. The cost per volume is actually ½ of that of the ordinary current novel.

Due, however, to continually rising manufacturing costs, we expect these prices to be effective for only a limited time—SO WRITF TO-DAY FOR INFORMATION.

THIS FAMOUS LITTLE BOOK FREE!

FIFTEEN MINUTES A DAY always finds a cordial welcome on library table. Thousands of modern people have read it from cover to cover with absorbing increast. It gives De Eliot's own plan of reading. It is packed with helpful, practical information. You really can't afford to mass this little gem of literature. You'll receive this beautiful book without charge after you fill out and mail the coupon below.

NO one needs to be reminded of the important part played in modern water by the sirplane; newspaper stories are a constant reminder. The other side of the question, that of defense against the frightfulness of air raids, is equally important. It is vital to every nation that anti-sircraft guns be provided in efficient types and large numbers. The United States is, therefore, rapidly adding to its stores of guns, for defense against attack from the akies by a possible future enemy. Rapid and accurate fire characterize this deadily weapon for defense.

Personalities in Industry

Title automobile business has made the most amazing progress of any industry in the past two decades—and the least known part of it—the human side—is one of the most fascenating, stories in American business. For the automobile industry is literally a self-industry in literally self-industry in literally a self-industry in literally self-industry in litera

Mr. Foy is president of the De Soit Motor Corporation, vice-president of the Chrysler Corporation, and secretary of the Automobile Manulacturers Assoit ton. And he started at the bottom—but he's never forgotten the things he learned about people when he was out on the firing line as an automobile salesman in the days when you not only had to sell a man a car, but also sell him the idea of why he ought to own a car at all!

As far back as college days, Byron Foy was what you might call an "automobile nut". He had a httle four-cylinder car and he loved it. In fact, he liked cars so well that when he graduated he went to work as an automobile salesman in a Dallas factory branch, but he didn' wait around the sales finor for people to come in. He went out and made calls last af them.

When the company announced a nation-wide sales contest, Foy decuded he would have to sell in volume, if he was to compete against salesmen an the larger cities. Thus he went out after feet business—large corporations and on the city itself. Like the rising young a main in the popular Alger nowle of the day, Byron Foy won a coveted prize in that contest.

Then the factory sent him east as a traveling representative His eastern dealers said they couldn't sell cars in winter. "We can't make country deliveries in the snow," his men complained "Why not deliver the cars on sleds'"

BYRON C. FOY

Foy suggested And they were delivered, right to the fariners' front door. Sales increased.

Still later Foy went to the Pacific Coast and subsequently became presdent of the Reo Motor Company of California Later he returned east as a partner in the New York Chrysler distributorship.

Here he came to the attention of Walter Chrysler, noted for his encouragement of young blood in his organization. Walter Chrysler recognized Foy's promotional instincts and sound busi ness judgment, and brought him to staff headquarters. Under Fov's leadership. De Soto has become a potent factor in Chrysler Corporation sales, and when you talk with Byron Foy, you'll know just why. The fact that he knows people-the things they want and the motives that make them buy-is reflected in his talk, as well as his products, his advertising, and his relations with his men and his dealers.

There's nothing fancy about Byron boy's office, or about Byron Foy The office is sumply furnished. Papers never stay on his desk very long Foy is a bear for detail- but he goes straight to the most important tasks first talks easily, and he is easy to talk to. He believes in giving his executives complete confidence and responsibilities. Thus he not only surrounded himself with a strong staff, but the way in which he operates has helped make them strong Byron Foy is married, and has two children. Besides his family, his main hobby is still motor cars. Though for sheer exercise he rides horseback. the wheel is still his first love. De Soto salesmen in New York know that they can always "call Mr. Foy's office" when a little extra help is needed to make a De Soto sale to one of Foy's many friends. For Byron Foy, automobile company president, is still a great automobile salesman who gets a kick out of "closing a deal."

50 Years Ago in . . .

(Condensed From Issues of December, 1889)

CANNON—"The Spanish government, determined to emancipate the country from its dependence upon foreign nations for its munitions of war, has of late years displayed great enterprise in the establishment of works for the building of war ships and

cannon Among the guns lately turned out at Trubra are four which form part of the armament of the new Spanish steel cruiscr Pelavo Of these two are 49 ton 13 in guns and two are Il in Onc of the 49 ton guns, shown in our en graving, was lately proved The projectile used was of steel, weighing 960 lbs., fired with a charge of 440 lbs. prismatic powder, which gave an initial ve locity of about 2000 ft

TRANSATLANTIC. "The steamer (A1) of Rome, on her last trip out, made the port of Milford Haven nastead of Lwerpool, the magnificent system of locks, long under construction at that port, having been at last completed. The substitution of Milford Haven for Laverpool as a terminus saves the delay in steaming up St. Georgie's Channel and up the Mersey, and, more important yet, avoids the dangers of the channel fogs and the annoying delayoff the Mersey Bar. To London from Milford Haven such between tunnel u 285 miles, against 201 from Laverpool, it heing 1½ hourlonger by rail"

COAL DUST - "Heretofore about one-seventh of the product of the coal mines has been lost in dust. It is now intended to utilize the dust by making it into bricks that will burn like hard coal, except that there are no clinkers as the bricks burn to ashes."

FORE-ST GIANTS—"Plying on Paget Sound is a boat 122 feet long. The timbers of which the hull is built run from stem to stern, and not one is spliced. As a specimen product a Washington lumberman sent to San Francisco last year a heam 24 inches thick and 152 feet long."

PHEASANT—"The Mongolan Pheasant, a valuable addution to our native game birds, was imported from China a few years ago it has increased with surprising rapidity in western Oregon, Washington, and in the northwestern corner of California, under effective legislative protection. The plumage of the male is extremely brilliant and attractive. As a table dish it equals the partridge and prairie chicken of the Fast.

LUMINOUS FOUNTAINS. "Among the most wonderful displays, electric and wasul, at the recent French exposution were those pertaining to the luminous fountains, which were arranged on a grand scale. The claimeleous like changes of color in the fountain waters were wonething astonishing to behold. It was not accomplished by the mere throwing of colored lights upon the exterior of a spouring jet, but was due to an interior electric illumination of a spouring jet, but was due to an interior electric illumination and improved within the crystal wall of the water and then carried along with it, becoming visible by interior reflection during the discharge of the water."

PHONOGRAPH INSTRUCTION—"Edison's phonograph has scarcely, as yet, passed the period of "novelly and curiousty," but many practical applications of the instrument have already been auggested, and have in some cases been actually carried out There

so one application, however, that we have so far not heard mentioned, and that is the instruction in the pronunciation of forcing lauguages. In the future the publishers of menuals of instruction in foreign languages will find it, most likely, a paying undertaking to publish a phonographic key of the various exercises, thus enabling of the various exercises, thus enabling the control of the control of the control tion and pronunciation of sentence until it has been perfectly initiated by himself."

LABOR SAVING—"Some people denounce labor-saving machines as an evil They notice that a few individuals are put out of work for a time by the introduction of some device, but they ignore the greater benefits which the whole community obtains."

LIGHTHOUSES—"The Lighthouse Board has submitted its report for the fiscal year ending June 30, 1889, to the Secretary of the Treasury At the close of the year there were under control of the board 1021 lighthouses and lighted beacons, 1328 lights on Western rivers, and 4289 buoys of varous kind. In the main tenance of these there are employed 1934 light keepers and a number of miscellaneous employees."

WAVES.—The height of sea waves has long been the subject of controversy. In the recent British scientific expedition some instructive data were gathered by a sensitive amend be aronetic capable of recording its extreme rae and fall by an automatur register. With a sea not subjected to an atmosphere of unusual violence, it indicated an elevation of 40 feet from the wave-hase to creat."

ARMOR-PIERCIN(—"The new British steel cruiser Blake is to be armed with handy rapid-firing guns that can penetrate 12 or 15 inches of armor plate."

FOOT-WARMER.—"One of the latest applications of electricity is the making of a floor mat that throws out heat—an electric heater, in fact, in the form of a mat. An excellent device for warming the toes."

BELL TELEPHONE SYSTLM

BALLOON MINES TO PUT THE AIR OUT OF ACTION

IF ferman bombers appear over London some dark night, they may find above, below, and around them an inescapable aerual mun field consisting of myrasds of small, free bellouns sent to a predetermined height and drifting with the wind Each would support a cannister of high explosure on 40 lect of fine seel wire. Enemy planes would, therefore, face the double danger of fouling their propellers with wire

and contacting the bomb itself. If a wire should catch on a wing, the bomb would be whipped backward to explode against the plane. A time fuse on the bomb allows it to become "alive" only after ade launching and puts it out of action after a given time. This aerial mine has certain dis action after a given time. This aerial mine has certain dis advantages, but it affords, according to H. G. Wells, "the possibility of putting the air out of action whenever we wish it." Invented by Major H. J. Muir, it would have an enormous effect on the morale of enemy raiders. Drawing courtesy The Illustrated London News.

Loading bombs in a U S. bombing plane during recent maneuvers

WILL BOMBS DOMINATE?

ERIAL bombing has become a naval A and military science of dominant importance in offensive warfare. This is attributable mainly to development in aircraft in regard to range, speed, and carrying capacity. Until near the end of the World War in 1918, aerial bombing was a very secondary means of offense compared with aerial machine gunning, which was organized for inter-aerial combat and occasionally used against troops deploying in the open. The airplane, at this time, was not a high-caliber offensive weapon. Today, the aerial bomber has become a supertype of long-range heavy artillery and a significant challenge is now being made to establish its efficiency not only against the strongest land fortifications but also against fleet battle-units and submarines. Recent events indicate that the command of the seas may to some degree be passing over to the nation which can hold command of the air. Should such power emerge, the aerial bomber will have become a primary offensive weapon in general warfare.

Aerial Bomber Has Become Super-Type of Long-Range Heavy Artillery . . . How Bombs Differ in Their Penetrating and Explosive Action

By ARTHUR E. OXLEY, M.A., D.Sc.

Multiple-engined heavy bombers, numbered internationally by thousands, can now carry projectiles, each weighmg a ton or more, over land and sea defenses which are far out of range of the most powerful military or naval guns Such projectiles are equipped with armor-piercing devices for hurling on ships and fortified positions; they explode with a delayed action after penetrating the objective Other projectiles are equipped so as to produce a "scatter" effect over the widest range possible; they are designed to cause the greatest devastation in troop concentrations deploying in the open or on unsheltered civilian populations. Such

projectiles explode instantaneously on contact with the objective.

High-explosive bombs may be classifed in two general groups according to their penetrating and delayed explosive actions or their non-penetrating and instantaneous explosive actions. The first has a relatively thin shell and a penetrating nose-cap of solid steel; the second has a thick shell for more deviasting ingeneration effect and a blunter nose to counteract penetration. There are many types of bomb in each classification and those illustrated diagrammatically in Figures 1 and 2 are intended merely as examples to indicate the general difference in the two classes.

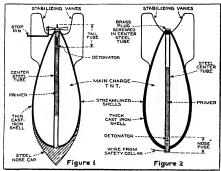

Figure 1 shows general details of a penetrating type of bomb, in which the fuse action is delayed Figure 2 illustrates a nose fuse type for instantaneous action

The type of fuse used in the bomb shown in Figure 1 is a delay fuse inserted in the tail of the bomb; that in Figure 2 is an instantaneous fuse fitted into the the nose of the bomb. (A delay fuse may also be fitted into the nose of a bomb but its construction must be different from the type shown.)

THE delayed action bomb penetrates and is used in attacks on ships or on towns where the structures are several stories high and are more or less strongly reinforced. Such a bomb, if dropped from a height of 10,000 feet, strikes the object at about 800 feet per secondmore than 500 miles an hour. On striking, the bomb does not explode immediately. It penetrates the roof and may pass through three or four floors before the fuse explodes it. The reason for this delayed action is shown in Figure 3. a diagram of one type of tailfuse. The bomb can explode only when the striker-pin punctures the detonator cap. When the bomb is fused, the striker pin is held away from the cap by a collar to which is attached a pair of vanes. While the bomb is in its carrier on the airplane, these vanes are prevented from rotating by a stop pin fixed to the carrier (Figure 1). As soon as the bomb is released, the vanes rotate, owing to the rush of air past the bomb. After the bomb has fallen about 100 feet below the plane, the vanes fly off the screw-spindle. To prevent the strikerpin from prematurely piercing the detonator while the bomb is in the air, the striker rides on a coiled spring as the bomb falls. On impact, the bomb is slowed considerably while the plunger carrying the striker has nothing to stop it but the resistance of the spring. The merta of the striker therefore compresses the spring and, in a small fraction of a second after impact of the bomb, the pun pierces detonator and the bomb explodes. This small delayed action is sufficient, however, to allow the bomb, because of its terrific speed and penetrating cap, to pass 20 to 50 feet made a building, according to the nature of its construction, before exploson takes place. Thus the structure collapses from the pressure of the confined blast.

In addition to the objectives already cited, deep trenches and air-raid shelters may be successfully attacked by bombs so fused.

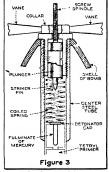

The instantaneous fuse used in the bomb shown in Figure 2 is designed to cause the greatest possible spread of the bomb fragments, by the explosive blast, so over the surface of the terrain attacked, the thick shell is shattered into chunks of metal which sweep over a wide area as the high-explosive is defonated. A type of nose fuse used for such a purpose is shown in Figure 4. The instantaneous explosion resulting is far more devestating to exposed personnel than would be the delayed explosion described above.

The nose fuse shown has no spring, Instead, a plunger is held securely in position by a copper pin, about 1/8 of an mch thick, which passes through the plunger and the walls of the fuse. While the bomb is in its carrier on the airplane, the fuse is kept "dead" by a safety collar which is slotted and inserted between the body of the fuse and a pressure plate. This collar is attached to the bomb carrier (see Figure 2) and is a secure protection against premature detonation even should the bomber crash efforts of the protection against premature detonation even should the bomber crash

on taking off. As the bomb is released, the safety collar is withdrawn. On impact, the pressure plate is arrested. The shock which it thus receives can be transferred to the detonator only through breakage of the copper pin which is incapable of withstanding the tremendous momentum of the whole bomb. The result is that the copper pin is instantaneously sheared off and within less than a hundredth of a second the striker pin pierces the detonator which causes explosion. Owing to the almost instantaneous action of this fuse, the explosion makes only a very small crater -perhaps one to two feet deep on average ground for a bomb weighing 100 pounds. Under similar conditions the same bomb, fitted with a tail fuse, would make a crater about five to six feet deep. Figures 5 and 6 show this difference, With a tail fuse, the bomb is almost buried in the ground on explosion and the blast is localized With a nose fuse, the bomb is almost entirely above ground and its blast is wide-spread.

WHEN bombing from low altitudes, as was done over the countryside in Poland, an additional slow time-fuse must be inserted between the striker mechanism and the detonator. On release the bomb travels forward with the same velocity as the autipliane and the additional delay of at least several seconds, given by the time fuse, allows the bomber to get clear of the danger zone before detonation takes, place.

The main filling charge of modern high-explosive bombs is relatively insensitive. Tri-nitro-toluene (T.N.T.) and various mixtures of this with ammonium nitrate, itself an explosive, are the usual fillers. The mixtures are known as "amato". Sometimes a small

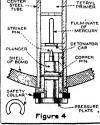

Details of a tail fuse

percentage of powdered aluminum is included in a filler called "ammonal" which has a higher temperature of detonation. Without the use of a detonator none of these explosives will function even on impact of the bomb from several thousand feet. Even the detonator, containing a few grains of fulminate of mercury, which explodes violently on shock, is not a certain guarantee of detonating the main filling charge. It is customary, therefore, to employ a primer consisting of an explosive more sensitive than T.N.T. but less so than fulminate of mercury, to boost the detonator and effect the complete detonation of the filler. In serial bombs, this primer is charged with (tetra-nitro-methyl-aniline), "tetryl which, like T.NT, is a dye-works byproduct. The general manner of assembly of detonator, primer, and filler is shown in Figures 1 and 2

FOR modern incendiary bombs, a most effective filler is thermit. This consists of a mixture of powdered aluminum and magnetic oxide of iron, and is commonly used in welding. When it is fired through a magnesium primer which in turn is ignited by a phosphorus coated friction strip, a temperature of from 2300 to 2500 degrees, centigrade, results-a temperature which easily melts steel Thermit does not depend upon a surrounding atmosphere of air for its action-the oxygen in the iron oxide provides this, uniting rapidly with the aluminum and causing the tremendous rise in temperature The mixture will burn under water, boiling it fiercely. Water is uscless to extinguish the whitehot slag-it merely passes into scalding steam. Sand is best for localizing the incendiary action

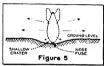

Modern incendiary bombs are very small: about six inches long and threequarters of an inch in diameter. They are provided with heavy penetrating iron nose caps and small fixed tail vanes. Containers, each filled with several hun-

Details of a nose fuse

dred bombs, are discharged as units. On their downward flight they scatter, since they are poorly streamlined, and cover a wide area of the objective. Hundreds of ferce small fires are thereby stated, and any attempts to control the general conflagration are made extremely difficult owing to the numerous scattered outbreaks. If such an incendary raid is immediately followed up by a raid with high-explosive bombs, and possibly also a gas attack, no fire personnel or equipment can cope with

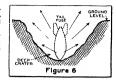

Among bombs used in gas attacks, the most effective are those filled with "mustard gas," which is a liquid. When burst by a small powder charge, the heavy high diffuses into the ground and, for days after the attack, is dangerous to anyone in the locality. Where the temperature rives locally, unexpected vapors emerge and may descend into the deepest dugouts and shelters. This wapor acts slowly on the eyes and lungs it has practically no smell and long it has practically no smell and long after a raid unsuspecting persons who

A bomb fused at the nose explodes on contact, spreading a wide blast

chance to remove their gas-masks—as they must do sooner or later, either for nourishment or comfort-may be attacked without warning. Some hours later blurred eyes, lump bodies, and severely blatered skins show the results. This gas causes only a low mor tality but it is highly efficient in putting personnel out of action.

As the war develops, it is possible to make only a guess as to the limits to which chemistry and physics will be applied as aids to aerial "frightfulness." Rumors of the use of super-high-explosives spread 'round the world during the later aerial bombardments in northern Spain. Liquid oxygen was suspected as the component Cylinders of cellulosic material when dipped in liquid oxygen become virtually packages of dynamite and when freshly prepared have enormous detonating power But other attendant circumstances, particularly those relating to the high vulnerability of such explosives to shell and even bullet fire and to the evanescent power of the charge-due to continuous and unpreventable evaporation of the liquid oxygen-would seem to lessen the likelihood that such liquid-oxygen matrices could be of real military effectiveness. True may be the report

Penetrating deeply, the blast of a tail-fused bomb is more localized

that the explosive used was "obtained from the air"—but so are the ammonia ingredients used in "amatol" and "ammonal" high explosives obtained by the nitrogen fixation process.

There is also the possibility that concentrated effort is being made to seek a practical application of what has been called the greatest scientific discovery of the year—the detonation of atomic energy as exemplified in the selfcatalyzing fission of uranium and other substances, the neutron bombardment.

LAST, we cannot completely ignore the possibilities of biology. Reports are available that much experimental work has been done on the possibility of employing bacteria as a novel kind of "ammunition." In this connection, Wickham Steed has called attention to the activities of the aerial offense section reported in Luft-Gas-Angriff of the Berlin War Office. In 1938, General Chu Teh reported to the League of Nations that the Japanese had used bacteria in four central China provinces. These try-outs may have shown either the present impracticability or the dangers which attend such desperate means, but modern civilization cannot entirely shut its eyes to the possibilities of future research in this field. The biological view indicates that the effective dissemination of a bacteriological fog of typhoid, anthrax, spotted fever, or plague would have to be carefully synchronized with exacting conditions of temperature and humidity to insure survival of the germs. The bacterial "bomb" apparently consists of a glass container filled with a prescribed culture which is floated by parachute control over areas far in the rear of enemy lines, a mechanical release being employed to release the contents either in the air or on ground contact. The available reports also indicate the "conscription" of infected vermin.

If such monstrous methods should ever become practicable at appears that the only means of defense both for the attacker and attacked would be an elaborate organization of all resources of prophylaxs. Probably a mere knowledge of the power of retaliatory measures, even should such attacks prove practicable, will be an adequate deterrent against such attempts.

ALL FOR ONE AND ONE FOR ALL

T is customary to think of that large group of companies which provides motor transportation for America. and for much of the rest of the world, as units in a number of industries—automotive, aviation, oil, tires, parts and accessories, and so on. Actually, this entire group is one inter-related, interdependent industry, the problems and progress of which are inseparably linked Nothing illustrates this so well as their co-operative research activities. It is doubtful whether anything in American industrial life during the past ten years has been more significant than the freedom with which research men in this group have exchanged ideas and co-

operated in experimental projects. The fruits of this research have had a far-reaching effect. Better cars at lower prices, better gasolines at lower prices, better tires, airplanes. trucks, tractors, stationary engines, motorboats, and other products made by these companies have been in such demand in America that this closely associated group has grown to a point where it now employs the full-time services of between six and seven million people; furn ishes bread and butter for a sixth of the nation directly, and a considerably larger percentage if all those indirectly employed are considered Almost every person, young and old, has benefited to a greater or lesser degree through faster, safer, more comfortable transportation

Much has been written about modern research methods, but most of it remains incomprehensible to the average layman. When John Q Public makes what he imagines is a firel econ omy test, he tries out three or four brands of gasoline and, the the basis of the most casual

draing, decides that one is better than the others Of course, such a "test" has no scientific basis. When research mentackle such a problem, they eliminate take into account every variable, such as the air pressure and diameter of each tire, himidily, temperature, and barometer readings for the day, the condition of the road; the velocity and angle of the wind, and the manner of arceleration and deceleration

Even one variable, the manner of driving, can make as much as 100 percent difference in miles per gallon. In a recent experiment in Detroit, two cars of Research in Motor Industry . . . Co-operation and Exchange of Ideas, Findings . . . Has Resulted In Numerous Significant Developments

By J. J. FREY
Engineer in Charge of Technical Salas Division

the same make and model, both just of the production line, were driven in city traffic over the same route. One driver was told to "step on it" at green lightand to drive as fast as the law allowed until he had to put on his brakes for the next stop light. The other was told to accelerate and decelerate gradually, to make as little use of the brakes as nos

After this laboratory test of an engine, on which is mounted a V-belt driven supercharger, the engine will be installed in a truck for extensive road tests

sible The first car used twice as much gasoline as the second in covering the same distance!

Let us look, then, as an example, at how one group of research engineers made a fuel economy test First, they searched for an absolutely level place where they could run cars at steady speeds and at pre-determined varying speeds without interference. This they found in the middle of the Mojave Desert in California—the tuble-flat bed of a dry lake. Next they devised an instrument which would measure and record the velocity and direction of the

wind at all times, a fifth wheel, which would overcome the variable of tire slip page, was installed and attached to a recording device to show exactly the distance traveled over land as compared with the distance traveled through air, asmeasured by an anemometer. Fuel wasfed into the carbureter through graduated gages which measured the gasoline

in cubic centimeters. Humidity and temperature records were calculated at all times. The tests were run over and over in order to average the errors which the engineers knew would still creepinto the calculations. Altogether, the work covered a period of months and cost several thousand dollars.

7 OU may well ask who went Y OU may well as did it prove The answer goes to the very heart and spirit of the group which furnishes the vehicles, the tires, the gasolines, the parts and accessories, right down to the last gadget used in motor transportation Fuel economy is the concern of many groups and literally hundreds of companies. The company which made this economy test manufactures tetraethyl lead, which is used by oil companies to im prove anti-knock quality of their gasolines. But the data

obtained were of interest to dozens of companies, showing, as they did, pertinent figures for what engineers call optimum compression ratios, carbureter settings and fuel anti-knock requirements of particular types of engines.

Although several companies often take part in one co-operative research program. I must, for obvious reasons. confine examples to the part of such projects about which I have personal knowledge and which concern, as above, the research activities of a company that manufactures anti-knock compounds for gasoline.

Some of the most interesting, and at

times, most difficult parts of research or projects are the development of devices properly of the development of devices opened of instruments to measure pertinent variables. No laboratory can infunction without instruments and, strange as it may seem, very few of the migration of the purchased. When such instruments are needed, there is usually only one way to work of the problem—uvent them. A few properties of the problem—uvent them.

In one of our research projects, we wished to measure the air-fuel ratio in each of the individual cylinders of an engine. No instrument for such measurement urement existed, or if it did, we could not find it. So our engineers devised a set-up which enabled us to trap a sample of the combustion products of each cylinder and analyze them. In the same project we wished to find out the exact instant when each cylinder fired. The instrument finally worked out recorded the ignition timing on cincina film Sometimes a research project becomes so involved that the engine being studied is converted, for all intents and purposes. into an "instrument." Such an "instrument" looks like an ordinary heavy-duty truck until you get into the cab or lift the hood. The average truck driver would find gages, dials and gadgets he had never seen before Under the hood he would find that each set of three cylinders had its own fuel system, and many other modifications This "instrument" took several months to assemble and build and cost over \$10,000, but it proved immensely valuable in tests where it was necessary to eliminate the variables that always must occur when the performance of one truck engine is compared with another

7ITH proper instruments, technically able and intelligently farsighted research workers, given sufficient time and resources, accomplish feats that in the aggregate become gigantic For example, 15 years ago, the engine of the average American automobile had a displacement of 252 cubic inches and could develop 59 horsepower. The average 1940 automobile engine has a displacement of 255 cubic inches. almost identical with the engine of 15 years ago, but it can develop 106 horsepower. Thus we see that in the short space of time that anti-knock compounds for gasoline have been available, the horsepower developed by the average American automobile has been increased over 80 percent, while its weight has remained approximately the same. A large part of the increase in power has been gained by increasing the pressure on the gasoline vapor in the cylinders before it is burned, which, in effect, squeezes more power out of each drop of gasoline. This is where the anti-knock quality of gasoline becomes important, for higher

Cathode-ray oscillograph for testing ignition system characteristics, and apparatus to determine spark plug insulator resistance and minimum firing current

anti-knock quality is required if gasoline is to burn smoothly under the stress of great heat and pressure inside a cylin der

Seems to be a simple matter, doesn't it! Use gasoline of higher anti-knock quality, squeeze it a little righter in the combustion chamber by mercasing the compression ratio and picsto, you get more power and better economy Unfor tunately, it was not as easy as that A multitude of problems had to be solved before this happy result was achieved It is more or less a truism in research that when a change is introduced to solve one problem five or six other problems may be created That was what hap pened when compression ratios were moved up Research and experience showed that the compression ratio which may be used with a given fuel is influenced by many variables including engine design, cylinder size, materials of construction, carbonization rusting and liming engine speed, jacket temperature, mixture ratio, mixture tein perature, volumetric efficiency and ignition tinging

Ingineers spent years studying these variables as well as the relation of compression ratio to bearing pressures valves, spark plugs, and so on Hundreds of tests were run on high nedium, and low compression engines, both in the laboratory and on the road. Literally thousands of adjustments and re-adjust ments were made

all this work eventually led to the universal utilization of higher compression pressures and higher compression pressures and higher compression ratios in passenger car engines. The average compression pressure in the 1931 automobile was between 90 and 100 pounds per squares inch. Today the average is between 140 and 150 pounds Average compression ratio in passenger automobiles in 1925 was 4.5 to 1. By 1931 the average had risen to 5.25 to 1

Today at is 6.28 to 1. Optional compression ratios micendership higher. One manufacturer has available a cylinder bend group 7.45 to 1 ratio. And tests have been run in the laboratory on enciences with compression ratios as high as 11 to 1. The net result, as pointed out above, has been more power and better economy with very little increase in encience with compression ratio or produced to the property of the produced of the

BUTs such results would not have been possible had not the 'oll companies kept in step with the march of progress by improving the anti-knock quality of gasolines year after year. Butter cracking processes, polymerization, selection of crudes, blending, and the addition of crudes, blending, and the addition of trate-thy lead have provided the fine fuels at low out which have justified car manufacturers in designing popular-proced cars which reach ever higher plateaus in engine efficiency.

And this parade of progress has not stopped Supercharging for the average car may be the next step which automotive engineers take to squeeze more power out of better gasolines, and so our research workers for the past several years have been experimenting with the possibilities and problems of supercharging. In one test, a stock eightdoubled its power output after being eylinder passenger car engine almost supercharged The engine had an orig inal compression ratio of approximately 51/2 to 1 and developed 82 horsepower at 4000 r.p m. using fuel with an anti-knock quality of 78 octane number. After it was supercharged with an intake manifold pressure equal to 10 inches of mercury, it developed 160 horsepower, using gasoline with an anti-knock quality of 90 octane number. To carry this test further and to determine what advantage supercharging could give to this

Car with anemometer and fifth wheel speedometer. The former determines wind direction, velocity; the latter gives an accurate speed reading. At right Instruments within the car for use in conjunction with those shown above

engine without nequiring a fuel of greater octaine number than that onginally used, the compression ratio was lowered to 4.25 to 1. Using 78 octaine fuel again, but supercharged to 10 inches of mercury, the engine developed 63 percent more horsepower than it had with the higher compression ratio on the same fuel.

Thus supercharging, which simply means forcing more an and fuel vapor into the engine by putting greater-than atmospheric pressure on the intake mani fold, seems to promise more of the same kind of improvement that was effected by increasing compression ratios But there are still a number of problems for research workers to solve before all of the hoped-for gains in efficiency can be realized. For example, in the tests in our laboratories we could put any pressure we wished on the intake manifold at any speed because the engine was on a stationary mounting, taking its air from a tank where constant pressure could be maintained The problem of achieving equal control with a blower driven by the engine being supercharged is quite another matter. Other laboratories in the research departments of automobile companies, and manufacturers of superchargers, are working on this problem now We are co-operating with them. giving them the results of our work and they giving us the results of theirs

But what will be the effect of such great increases in power on other parts of the engine? Will present engine steels, stand the gaff? Take valve steels, for example. Fifteen years ago, cast iron was used for exhaust valve heads in mans engines Increases in compression prasure and more revolutions per minute made it obsolete. Sitch-rome steel heeame the standard. Today, with still furtiler demands, Stelline-faced valves have comto prominence, and with all the heat and pressure of modern high-speed operation they will open and close (and make a tight seal) 10 to 20 times a second for hours on end while you buzz merrity along without ever a thought of 1,300,000 jobs each valve is sesigned to do in your engine every thousand miles

What about spark plugs? Will supercharged engines call for still further improvements here? A spark plug that wasatisfactory in the car of 1925 would not last 15 minutes in a 1940 car running at wide open throttle Years of experimentation and testing have given the answer to the question of how to make them in satisfactory for today's car. What about to tomorrow? Only research, trial and error, and trial again can supply the

WITH this past experience in mind, it is easier to understand why super-charging is today of interest to many companies and many research workers and why they swap knowledge and conserve time and money by cooperafive work. When you start changing the character to fineresic gasoline engine, or start changing the character of Jenerosic gasoline of its gasoline, you interest everyone in a group of industries employing literally billions of dollars.

Even when the finished product is in the hands of the ultimate consumer. many organizations in the vast automotive transport group lend a willing hand in solving problems in operation that may arise. A typical example with which I am familiar was a bad case of what the trade calls "tail pipe halitosis" experi enced by a large city bus company. The situation reached a climax in November. 1936, when civic organizations de scended on the company and demanded that something be done to stop the fumes of acrid smoke pouring from the exhaust One of our service engineers, a veteran of innumerable tussles with hus and truck problems, offered his services. The bus company furnished him an engine of the same model used in the buses and it was set up in our Detroit laboratory. After several weeks of experiments and tests, he worked out a procedure for correcting the trouble and presented it to the bus company. The officials tried at out on ten buses, found that it worked and eventually changed over their entire flert. His recommendations—moreosed untake manifold temperatures, changes in carbureter characteristics, including leaner offle mix-acteristics, including leaner offle mix-

tures—have been adopted by other bus companies and today are standard practice in meeting the condition known as "tail pine halitosis"

Another field in which the continuing efforts of research have led to tangible results is power farming. Five years ago. all tractors were equipped with "compromise" engines-that is, they were designed with low-compression motors to burn kerosene, distillate, or gasoline But farmers who burned gasoline in their tractors got only part of the potential power in the fuel. Why not build tractors with high compression, automobile-type engines capable of using gasoline efficiently. This would give the farmer something he wanted. Tractor engineers who held this belief found ready assistance in our engineering laboratories. The advantages of high-compression tractors were determined by the laboratories and explained to the farmers and tractor dealers. Today nearly all tractor manufacturers make high-compression tractors.

As the new 1940 cars go on the market there are improvements and refinements not available on cars of previous years. Three changes represent a cumulative total of thousands of hours of recease labor in a hundred different laboratories.

The same impelling force and relentless research which have given us today's engines and vehicles will push on to discover and utilize better principles and materials for the motor transportation of the future.

OUR POINT OF VIEW

No Vigilantes

TIMES of national stress alwaysbring with them curious and often dangerous personal reactions. Mass hysteria, fostered by ill-founded rumors and frequently by malicious gossup, was the cause of many a vicious outburst during World War I. Spy sares set neighbor against neighbor, created suspicions that often had no more foundation in fact than a foreign-sounding name.

With present unsettled conditions pointing toward a future that cannot be predicted, it is comforting to know that our national security has been placed in the capable hands of the Federal Bureau of Investigation This organization, with the co-operation of all law-enforcing agencies throughout the nation, should certainly be able to cope quickly and effectively with internal affairs that might have disastrous effects of permitted to get out of hand.

Speaking of this latest job of the F. B I., Director J. Edgar Hoover recently sounded a warning that, heeded, will assist greatly in keeping the United States on a level keel during troublous omes "In the wave of patriotism that is rising in the country," said Mr Houver, "there lies the danger of overrealous groups or individuals engaging in acts which are distinctly un-American in method, no matter how patriotic in aim. We need no vigilantes in this situation The vigilante method is disunctly contrary to American ideals of justice. The Federal Bureau of Investigation has been called upon to investigate all matters relating to espionage, sabotage, and violations of the Neutrality Regulations. In turn, the Federal Bureau of Investigation has requested co-operation of all law enforcement officers in the United States.

"This combined attack by Federat and State forces should be sufficient so far as investigation and prosecution are concerned." Mr. Hower continued. "Beyond the efforts of these law enforcement agencies there is a need, of course, for the individual co-operation of all suncer and carnest Americans. This co-operation should be limited, however, to passing on to the proper officials all questionable facts or rumors which may come one's way. An alert public is the best defense against traitorous or imminated conduct. Let us be realistic and practical. but always calm in our judgment between the real and unreal."

Thus each individual citizen is squarely faced with his own share of the problem of controlling traitorous acts, yet adequately warned against actions that might not only hamper the wheels of justice but even render them momentally ineffective—A. P. P.

Modern Pioneers

NOT so many years ago this nation celebrated 150 years of existence by the Sesqui-Centennial Exposition Next year it would be fitting if we should have another sesqui-centennial celebration, one that would mark one of the few extremely significant milestones in our lustory the founding of the American patent system. Our progress has licen keyed largely to that system and the incentive which it has given to individuals to originate, develop, and improve those brain-children that have made this country the greatest industrial nation on earth. Had it not been for the granting of patents and the profits therefrom our neople would not now have the most advanced civilization ever known, nor enjoy the greatest number of conveniences, coinforts, and luxuries. we would lahor longer hours and have much less leisure time. Our patent system has been, indeed an important stimulus to invention, research, and in dustrial progress

It was with the thought that the American people should understand clearly the dependence of the nation on a sound patent system one that is not being changed constantly at the whim of would-be economists, reformers and malcontents-that this important anuversary is to be observed in 1940. The Modern Pioneers plan to mark the year by several interesting programs, the principal one of which will be the presentation of a number of awards to outstanding inventors and research workers Manufacturers and responsible executives or members of trade associations and scientific and engineering organizations are being invited to enter nominees for these honors. (Entry blanks may be obtained from Modern Pioneers, 14 West 49th Street, New York Closing date: December 1, 1939) Local dinners will honor selected local Modern Pioncers, and some time in February a national dinner, broadcast over a national radio hook-up, will honor a number of the country's outstanding Modern Pioneers.

That the whole program will succeed m its purpose seems saured by consideration of the Award Committee. It is composed of: Karl T. Compton, of M.I.T., Chairman; Forest R. Moulton, of the A.A.A.S.; George B. Pegram, of Columbia University; John T. Tate of the University of Minnesota, Edward R. Weidlein, of Mellon Institute; and Frank C. Whitmore, of Pennsylvania State College

We wish the organization the great success it richly deserves —O D. M

Not Poison

"THEY who get spanked" ninglit well have been the title of a brief item lost to the general reader by its inclusion on our Legal High-Lights page last month. It is here resurrected for the same non-legal reader because of its stat lument.

It seems that the Federal Trade Comterculating "from time to time") as to the injurious effects resulting from the total time to the season of the total time to the season of the publisher of the rumor "traces," charge ing that he deceives the public. To us this is a masteripace of understatement

This bare-faced campaign to instill an awful fear in the mind of the public has been going on for many years-not just from time to time. It has been fanatic Why no one knows. It has been insidious, powerful in its effect It has offered such a specious brand of "proof" that food cooked in aluminum acts as a slow poison or causes cancer or both that believers have carried on the cycl work by word of mouth. And the believers have not all been unintelligent, simply unwise. A cultured lady ouce told this writer of a trained nurse in a great city hospital (of all places!) who was suffering from a serious case of aluminum-cooking-utensil poisoning!

The fight against this foul campaign of fear has also gone on for years Scientific American has been in the thick of tlus fight, has patiently ex plained over and over that aluminum cooking utensils can have no injurious effects on those eating food cooken in then: In unequivocal terms, this maga zine has branded rumors to the contrary as malicious and entirely without foundation. We repeat the accusation. The American Medical Association, Mellon Institute, Government bureaus, and others have all done their share of the fightuig against the rumor, have done their utmost to scotch it. Yet even now. with the Federal Trade Commission lined up against the fanatics, some people will probably keep talking of the dangers of aluminum-cooked food. But then, they're probably born pessimists and think they have every ailment ever mentioned by Sister Sue and Grandpap and Aunt Het, anyway!-F. D. M.

WHAT'S INSIDE THE STARS?

THE recent Colloquium on Astrophysics, at Paris, under the auspices of the Foundation Singer-Polignac at which the writer had the good fortune to be present, will have a place in the memory of its participants something like that of the great international conference of the Solar Union at Bonn in 1913shining the more hrightly by contrast with the tragic days which followed. Unlike the earlier meeting, this was a small affair with only 16 regular delegates. and a scant dozen of other invited guests; but it was truly international. Seven countries were represented among the delegates, counting by present residence

-France, Belgium, Denmark, Sweden. England, Canada. and the United States Counting by country of birth, four more are to be added—Holland, Germany. Russia. and India — represented by astronomers of distinction, all of whom are now living in the United States!

The sessions—held in an excellent room provided by the Collège de France—gave much more time for the consideration of individual topics than is practicable at the larger congresses. One, or at most, two of the invited papers were presented at a session; the speaker had 40 minutes or so to present his conclusions, and almost as much time was often spent in animated and profitable discussion.

The problem of language-always more or less difficult at a truly international gathering-was very successfully solved All the speakers found it easy to present their views either in English or French, and their remarks were translated into the other language, sentence by sentence, as they went along, by a very competent secretary After a few minutes' experience, this proved remarkably simple; and, though of course it took time, it did not interfere with the free flow of thought and expression, even in active discussion (and the discussions were active) --- as many as ten members sometimes commenting on a single paper The scheme worked so well, indeed, that it may be commended in other cases where the language problem has to be met

The Colloquium confined itself to two subjects, more closely related than appears at first mention; namely, the novae and the white dwarfs. All the delegates spoke with authority in one or another part of this fairly extensive field.

Lundmark discussed the parallaxes and absolute brightness of the novae; Stratton, the evolution of absorption bands in their spectra; Edlen, the idenMost of Our Present Knowledge of the Composition of the Stars Concerns Only their Atmospheres . . . Now the Analytical Boring Machine Digs Deeper

By HENRY NORRIS RUSSELL, Ph.D.

Chairman of the Department of Astronomy and Director of the Observatory at Princeton University Research Associate of the Moint Wilson Observatory of the Carnegie Institution of Washington

infication of previously unknown lines and Mrs Gaposchkin a spectrophotometric study of the bright bands and continuous background

Beals considered the relations of novac to Wolf-Rayet stars, P Cygni stars, and stars with spectra like Alpha Cygni, and Gaposichin their relations to the SS Cygni variables

Swings spoke of the physical problems of the atmospheres of novae and similar stars, Strömgren of theories of their internal constitution, and Baade of the amazingly luminous supernovae

Turning from the hugest of the stars to the tunest, Kuper described the white towarfs and other abnormally flant stars, announcing the discovery of many new ones and discovery of the stars of the star of the st

O UR less technical readers may be asked to excuse this condensed list of papers. Every one of them contained things which can be presented in non-technical language, and are of general interest To describe them all would fill many pages like these At present, it may lie well to follow a long-established rule of these columns, and speak of work which has already been published, in part at least, in professional ournals.

The question of the composition of the great internal mass of a ster might be supposed to be inherently unanswerable. The spectroscope gives us a wealth of information about the atmospheres of information about the atmospheres of the stars, and hose established convincing evidence that they are, in general, very similar among themselves in composition (though not in temperature or pressure) and much like the Earth, except for a vastly greater abundance of hydrogen and helium

But the atmosphere of a star—which forms less than the outermost billionth part of us mass—may not be a fair sample of the whole. We can only "get deeper" (to use Eddington's phrase) by an "analytical boring machine." For an

ordinary star, the process is in outline

The central temperature of a star depends on its mass and radius, on the average weight of one of the free par ticles in its interior (atoms, electrons, and so on) and on the "model" on which it is built -that is, the way in which the density increases toward the center. The latter effect is found to be remarkably small-it takes an increase of density at the center to more than a hundred times the general average to get a central temperature twice that for a star of uniform density The average "molecular" weight is more important, for the temperature is proportional to it. At the center of a star the atoms are knocked all to pieces Hydrogen (weight 1) goes into two pieces (with an average weight of 1/2); helium, weight 4, into three (average 1 1/3); oxygen divides a weight of 16 among 9 pieces; iron one of 56 among 27 fragments (or under actual conditions a few less). For all sorts of atoms. except hydrogen and helium, the average weight of one of the dissociated particles comes out close to 2 (on the chemists' familiar scale); for helium it is two thirds as great as this and for hydrogen only a quarter

Hence, the more hydrogen there is inside a star of a given mass, size, and build, the cooler the star will be inside. The rate at which heat leaks out to the surface will be correspondingly smaller, and the star will shine less brightly Helium has a similar effect, but to a much smaller degree.

The analytical theory has been fully worked out-first by Eddington, and in more detail by Strömgren—and it is found that a sar containing no hydrogen should be about 300 tumes as bright but containing about 80 percent of hydrogen by weight. For almost pure hydrogen the true theoretical brightness rises again; but this does not concern us here.) The brightness of a star with a gwen hydrogen content can be calculated from pure theory—assuming a goed average "model"—and it is found

that such stars as Sirius, Capella, and the Sun are all much fainter than calculated for no hydrogen. Theory and observation agree for a hydrogen content of about 35 percent for all three stars. (This is hy weight; by number, the light hydrogen atoms form a large majority.)

Reasonable change in the assumed density-model might alter the calculated abundance of hydrogen by a few percent but would not greatly modify it.

Most of the stars for which the calculations can be made come out of about the same composition. There are a few exceptions For example, Zeta Herculis has very nearly the Sun's mass, twice its diameter, and four times its brightness—which indicates a hydrogen content of about 15 percent.

This method, applicable to ordinary stars, fails entirely for the white dwarfs, But, strangely enough, the hydrogen percentage in these can be found in an entirely different way. In a white dwarf the free electrons are degenerate-they are sammed together as closly as the fundamental quantum laws permit. Under these conditions, the pressure varies as the 5/3 power of the number of electrons per cubic centimeter. Given this law, and the average mass of matter per free electron, we can work out all the properties of the body, if we know the total mass, finding its radius, density and so on. The actual white dwarfs, being visible, and therefore hot on the surface, cannot be entirely degenerate, but there are good reasons for concluding that they are actually bigger than this theoretical limit by only a small percentage.

Now for the companion of Sirius-the most famous of the white dwarfs-observations have been made of the "Einstein shift" of the spectral lines predicted by the general theory of relativity. For any star, this shift is proportional to M/R (where M is the mass and R the radius). According to the theory just described, the shift, E, is given by the equation $E = C M^{4/3} m^{5/3}$ where m is the average mass per free electron, and C is a constant which can be accurately calculated. Now for a hydrogen atom m = 1, there being one proton per electron. For helium m = 2 (mass 4, 2 electrons) and for heavier atoms it is nearly the same. For a white dwarf star of a given mass, and composed entirely of hydrogen, the Einstein shift should be less than one third as great as for one made up exclusively of heavier atoms.

For the companion of Sirius, the observed shift is intermediate between the calculated values for these two cases, and indicates a hydrogen content of about 35 percent.

There is unfortunately no other white dwarf for which our present data permit a similar test. There is one (40 Eridan) B) for which we know the mass, but the Einstein shift has not been measured, and estimates of the radius from the spectral type are precarious.

At this point a complication must be mentioned. The question, what equations are to be used for a degenerate gas when the velocities of the electrons become comparable with that of light, is still vigorously under debate. Sir Arthur Ed-

Atop the physics building at the University of Minnesota this 12ton dome for a 10½-inch telescope is insulated against temperature changes by two-inch slabs of Celotex laid between Tacetton members

dington maintains that the same formula should be employed, almost all other physicists agree in adopting a different one. The discussion, which is intensely technical, leads to the very frontiers of fundamental theory, and neither party has yet convinced the other.

Fortunately for our present interests. Chandraschar, who has worked out the consequences of the alternative theory with great analytical skill, finds that it, tion, when applied to the companion of Sirius, leads to a considerable abundance of hydrogen. This conclusion appears therefore to be independent of the theoretical controversy.

But, if there is still about as much hydrogen in Sirius B (the faint companion) as in Sirius A (bright) the astrophysical consequences are important.

According to Bethe's theory, the stars derive their energy by converting hydrogen into helium, and it is only after the hydrogen is almost absolutely exhausted that they have any chance of contracting into the white-dwarf state. The existence of a single white dwarf contain

ing abundant hydrogen appears therefore to be a grave objection to the theory.

Eddington has, however, suggested a way out. In Bethe's theory hydrogen is turned into helium, not directly, but by the action of catalysts—carbon and nitrogen—which are regenerated at the end of the cycle, and so used over and over again.

Suppose, however, that in each cycle a small portion of the catalysts is used up. Then, though the process would be repeated many tunes, it could not continue mediantely. The catalysts might be used up before the hydrogen, the formation of helium, and the liberation of sub-stome energy, would substantially cease, and the star might shrink unto a white dwarf with a good deal of its hydrogen left—plenty of fuel, but mothing to hur ut with.

Those who have followed our recent presentation of Bethe's theory, will realize that only a very small change in it is required He concludes that the N18 nucleus may meet two fates N" + H1 = $C^{ii} + He^{i}$ and $N^{is} + H^{i} = O^{ii} + hv$. In the first case, carbon is regenerated: in the second, the very stable nucleus of common oxygen is formed, while the energy hy is liberated Now neither of these reactions has yet been observed in the laboratory (at least, when the writer last had access to scientific literature) Bethe, from rather general considerations, concludes that the first is many thousands of times more likely to happen than the second-in which case a small amount of carbon would catalyze the transformation of a very large amount of hydrogen But, if the second reaction had a probability a few percent as great as the first, the carbon and nitrogen might be used up before the hydrogen

UNTIL more is known, by observation or by the advance of nuclear theory, about these questions, the stellar problem must remain open.

One difficulty, however, vanishes. It was very hard to see how Strius B, which shines feebly and is working at a low rate, could have used up its hydrogen before Strius A, which is working far faster The present answer appears to be simple it hasn't

There are other possibilities. Eddingtion calculates that, in the intermediate stage of contraction between an ordinary star and a white dwarf, a star would reach its greatest luminosity and its highest central temperature when it had shrunk to only about twice its final radius. Such a star would appear intensely blue-white, and have a central temperature of 150,000,000 degrees or more, and a very high density. Mether, under such extreme conditions, some of the heavier elements could be built up, is another problem for the nuclear physisist — Pordeaux, France, September 11.

Is Light Slowing Down?

THE third letter of the alphabet, c.

Is harmless enough in the normal course of things, but in the hands of scientists it has become a hook on which can be said to hang the whole of modern physical science. For scientists have chosen this little letter to represent one of the most important constants of the universe—the velocity of light.

In almost every fundamental physical equation, whether it be concerned with the structure of the atom or the rate of expansion of the universe, whether it deals with the energy of X rays or the mass of a rapidly moving body, the letter c will occur. Way back in the middle of the last century, James Clerk Maxwell showed by a brilliant piece of

mathematical analysis that all electromagnetic waves — X rays, ultra-violet rays, infra-red rays, radio waves—would travel in a vacuum with the velocity of light, and that this velocity was equal to the ratio of an electric charge measured on the electromagnetic system of units to the value of the same charge measured on the electrostate system.

Near the beginning of the present century. Albert Einstein, in his theory of relativity, indicated that the velocity of light was the maximum possible velocity attainable in the universe, and that the velocity of light in a vacuum would be the same for all observers. This velocity was no mere ordinary physical constant, like the velocity of sound, the viscosity of water or the density of lead. It was a constant which it was imperative for science to determine with great accuracy. Römer, a Dane, had been the first to do this successfully. Previously, in the 17th Century, Galileo had tried to measure the velocity by means of distant observers who uncovered lanterns but, naturally, his method was far too crude for him to obtain any results. Romer used the diameter of the Earth's orbit round the Sun as the distance to be covered by the light, while the required signals were provided in the eclipse by the planet Jupiter of his satellites. Römer's method was only roughly accurate, and during the 19th Century Some Physicists Suspect that Changes Occur in the Velocity of Light . . . Difficult to Prove . . . On the Whole, the Ouestion Remains Wide Open

By DOUGLAS W. F. MAYER

mechanical methods were devised and scientists in all parts of the world spent years in making observations and obtaining as accurate results as possible.

Nearly all methods used were modifications of two basic methods-the Fizeau toothed wheel and the Foucault revolving mirror. In the former system, light is passed between two teeth of a rotating gear wheel and reflected back from a mirror at the distant end of the base-line. The observer adjusts the speed of the wheel so that, by the time the light has been reflected back, a tooth has moved round and cuts off the light. Knowing the length of the base-line, the speed of the wheel and the number of teeth on the circumference, the velocity of light can easily be calculated. In the second or revolving mirror method, light is reflected from a revolving mirror along the base-line to a distant reflector and back again to the revolving mirror. By the time it gets back, the mirror will have turned through a small angle. This will cause the light to be deviated. By measuring the angle of deviation with a graduated eyepiece, and knowing the speed of rotation of the mirror and the length of the base-line, the velocity of light may again be easily calculated.

DY the beginning of the present century, a large number of results of similar tests had been published, and these garte the velocity of light with varying degrees of accuracy. These results were copied from the papers originally published, but often the copying was done inaccurately, and reappeared in textbooks and scientific journals. It was again copied inaccurately for later publications. Incidentally, these usually ignored the stated degree of accuracy (exchange debody of the mittal result.

In 1927, therefore, M. E. J. Gheury, de Bray, a London scientist, undertook the praiseworthy task of looking up and summarizing all the original reports of the measurements of the velocity. He published a list of these, but pointed out how inaccurate a good many of them were, and how many of the investigators had failed to apply important corrections. A strong test of the accuracy of a

scentific experiment is for the observer to take a large number of readings, and to exceed the control of the c

After carefully studying the subject de Bray came to the conclusion that, up to 1926, only seven really accurate determinations of the value of c had been made. He tabulated these as in Figure 1, in which the second column gives the base principle of the method used, whether toothed wheel or revolving mirror, while the final column gives the determined value in kilometers per second, with the degree of accuracy.

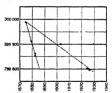

Figure 2: De Bray seeks explanation

De Bray was struck by the fact that here was a "constant" that was by no means constant, since its value seemed to vary from a maximum of 299,990 to a minimum of 299,796 kilometers per second-quite an important variation considering that c was supposed to be one of the fundamental constants of the universe. He accordingly decided to depict his results graphically, and obtained the series of dots shown in Figure 2. In this diagram the vertical scale represents the velocity of light in kilometers per second, and the horizontal scale the year in which the velocity was determined. Had the velocity of light

been constant, the dots should all have lain in a horizontal line. Actually, they appeared to lie on two oblique lines, as shown in the diagram. De Bray pointed out that the three on the left had been measured over relatively short base lines, while the three on the right had been measured over longer bases. Cornu and Helmert's reading seemed to fit in with both crows.

De Bray reluctantly came to the conclusion that those measured over short bases were probably less accurate than

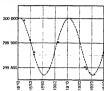

Figure 3 Edmonson's graph of 1934

those measured over long bases, and decided, for the time being, to ignore these readings. The other four readings seemed to show clearly that light was steadily slowing down at the rate of just under 4 kilometers per second per year. De Bray suggested this tentatively to the world of science, then deeded to savail further neasurements.

In 1928. Karolus and Mittelstaedt reported a determination of the velocity which gave a result of 299,778±20 kilometers per second and, in 1933. Peass and Pearson, continuing work Michelson had started at the Mt. Wilson Observatory, obtained a value of 299,774±11 kilometers per second This seemed to indicate clearly that the velocity of light was still decreasing, but the problem of the three "short-base" readings had yet to be solved.

Then, in May, 1934, Frank K. Edmondson, of Lowell Observatory, Arizona, suggested that the velocity of light may not be decreasing steadily, but might be subject to a periodic fluctuation. He suggested that a period of 40 years, with a maximum valiation of 115 kilometers per second above and below a norm of 299,485 kilometers per second, might fit the facts. Represented matter matically, this gives the formula

c = 299,885 + 115 sin 2x/40(T-1901) where c is the velocity of light and T the date of the year Represented graphically, the equation gives the simple "sine curve" shown in Figure 3. The nine dots on this diagram represent he nine accurate values then known, and the diagram shows how well they fit the suggested curve. At the suggested curve. At the sine has the superior could not be properly proved until about mill about the could not be properly proved until about

1938. If light were steaduly decreasing in velocity, the value of c, in 1938, should be about 299,760 kilometers per second, while if the velocity were fluctuating, as he suggested, in 1938 it would be about 299,835 kilometers per second.

The idea that the velocity of light might fluctuate slightly was borne out by the experiments of Pease and Pearson. In 1929, Prof. Albert A Michelson. undoubtedly the world's champion timekeeper of light, worried by the fact that tmospheric irregularities (the astronmer's "bad seeing") interfered with is measurements, using long base-lines. mbarked on the heroic task of con tructing a mile-long vacuum tube. The ead-straight, air-tight metal tube, three cet in diameter, and evacuated to a ressure of 1/250 of an atmosphere, was ud down at the Irvine Ranch, Santa un California Measurements undersken by the United States Coast and reodetic Survey revealed that the tube as 5230 76509 feet long, while by seans of murous, the light was reflected ack and forth along the tube cight times, giving a base line of about eight iniles. Three months after the tube was pnt into operation, on May 9th 1931 Professor Michelson died and the work was continued by Dr Francis G Pease, of Mt Wilson Observatory, and Fred Pearson, of Chicago University,

SERIES of 233 sets of measure-A ments was made over a period of two years, the results being tabulated in Figure 4 The final result was stated to be 299.774±11 kilometers per second At the same time, it was stated that the readings showed two periodic fluctuations in the velocity of light. One fluctuation had a period of 1434 days, the other of one year In both cases the velocity varied by about 20 kilometers per second. The shorter period fluctuation nearly vanished during December 1932 and January 1933, reappearing in February 1933. It was suggested that this fluctuation might be due to some influence of the Moon, though how such an influence might work is not at all clear. Reluctant to believe that the actual velocity of light was changing, the observers also suggested that the variation might be due to instrumental changes, such as a possible change in the length of the light path, ground disturbances, errors in the timing mechanism, or a possible effect of refractive index in the path of light. Whatever their causes, the existence of these minor fluctuations gave a certain amount of justification to Edmondson's theory of a long-period variation

De Bray pointed out that the earth's magnetic field, which is known to fluctuate, might have some effect on the velocity of light. Accordingly, experiments were made to see whether the

velocity underwent any change in a transverse magnetic field. The field used was 100,000 times more powerful than that of the carth, and the sensitive apparatus would have detected a change in velocity of one part in 20,000,000. No such change was detected. The suggestion that the refractive index of air might be changing was ruled out after referring to accurate determinations of this value made during the past 20 years

At the beginning of 1937, there came the news of another determination of c. made by Wilmer C. Anderson in the Physics Research Laboratory of Harvard University The method he used was to subject a light-beam to highfrequency modulations by passing it through a Kerr cell The light beam was then divided into two portions by means of a half-silvered murror, and the two parts were sent over different optical paths. They were recombined and focused on a photo-electric cell The difference in length of the two paths was adjusted until the photo-electric cell gave a minimum reading, indicating that the two halves of the beam were out of phase Knowing this path difference and the frequency of the modulation, the velocity of light was easily obtained

Between June 22 and December 5, 1936, 651 measurements were made, and showed no short period fluctuations which could not be attributed ducedly to physical sources. The mean result was 299,764±15 kilometers per second Later, in 1938, Dr. R. A. Houstonn of Glasgow University, Scotland, measured the velocity, using a piezo-electric crystal as an oscillator, and a base line only a few yards long. Initial tests gave a result of 299,760 kilometers per second.

These two determinations seemed to strike a death blow at Edmondson's fluctuation theory, so de Bray, deciding

again to neglect the early short-base readings, advanced a formula

c = 299,900 - 3 855 (T-1900) to account for the diminution of c This gives a decrease in c of 3.855 kilometers per second per year, and produces a straight line on the graph, as shown in Figure 5, which also shows the

readings now known — excluding, of course, the three short-base readings. So much for the experimental results. Meanwhile, what had the theoreticians been doing?

As was to be expected, the casting of doubt on something so fundamental as the velocity of light produced a veritable plague of theories, most of which were sooner or later proved either

to be untenable or to give a theoretical decrease in velocity of much less than 3 kilometers per second per year Most of the theories revolved around the supposed expansion of the universe. De Bray suggested that, if the universe were expanding, and if the ether were really material—a view still held by a few physicists—then the ether would gradually be decreasing in density, and the slowing down of light would follow as a matter of course. Calculations of the magnitude of such a decrease showed that it would be negligible compared with the decrease of 3.855 kilometers per second per year indicated by experiment. A similar theory was advanced by Edmondson, who suggested that doubling of the radius of the universe would cause the measured velocity to be halved. According to experimental results, however, the velocity of light should be halved in 60,000 years, whereas the universe is believed to double itself only every 1,300,000,000 years. From relativity considerations, Tokio Takéuchi, a Japanese scientist, deduced that the velocity of light will be decreasing, due to the redistribution of matter and radiation throughout the universe, but, again, the calculated decrease was far smaller than that suggested by de Bray.

OTHER scientists have been bolder. They realize that the only real evidence for an expanding universe is the shifting of lines in the spectra of distant nebulae toward the red end of the spectrum-the "red shift". Assuming that the velocity of light is constant, the red shift is explainable only by the theory that the sources of the light-the nebulaeare apparently receding from the Earth with enormous velocities. It has been

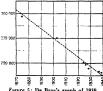

Figure 5: De Bray's graph of 1939

found that the velocity of recession is proportional to the distance away of the nebula, which gives rise to the picture of an expanding universe. The magnitude is such that nebulae at a distance of one megaparsec (3.26 million lightyears) are receding with a velocity of about 500 kilometers per second.

The bolder scientists point out that if the red shift can be accounted for by some other theory, then the nebulae need not be receding and the universe may not be expanding. Most of the theories advanced imply a change in the property of the light as it travels from the nebulae to the Earth, and several of these theories fit in with the idea of a decrease in the velocity of light.

One group of theories suggests that the energies of single packets of lightor "photons", as they are called-may gradually decrease during their journey through space, due to such causes as gravitational interaction, interaction with ionized gases which may exist in space, or simply by a gradual diminution of energy with time Such a diminution of energy would imply a diminution in frequency and, if the wavelength of the light were assumed constant, a diminution in velocity H J. Gramatzki has extended Maxwell's theory of light to allow for either a decrease of velocity with time or a change of dielectric constant with time. In both cases he showed that there would be a decrease in frcquency (that is, a red shift), and also in velocity, but again the effect would be negligible compared with that of de Bray.

Zwicky has suggested that differences might be detected between properties of terrestrial light and light from distant ncbulae. According to Pierre Salet, the velocity of light coming from stars is about 1 008 times greater than that of ordinary terrestrial light Zwicky has also suggested that the velocity of light may depend on its frequency, and that such a dependency would account for puzzling features about the spectra of certain novae Experimental tests, however, seem to refute this

In turn, de Bray himself recently came forward with a suggestion that the frequency and velocity of light may decrease with time, and claims that observed red shifts can be explained by a decrease given by the equations

case given by the equations

$$c = 299,774 - 173T$$

 $j = 762.2 - .4T$

where & is the velocity in kilometers per second, f the frequency in mega-megacycles, and T the time in millions of years. This represents a decrease in velocity of only one six-thousandth of a kilometer per second per year-which, of course, is much less than de Bray's former suggestion of 3.855 kilometers per second per year to fit the observed measurements.

Meanwhile, other scientists hold that changes in the measured velocity of light have no connection whatever with the expansion of the universe, or with alterations of certain fundamental constants. They believe that the variation is due to some undetected phenomenon which influences the apparatus in some way or another. They stress the discrepancies between observations over short bases and over long bases, and also point out that the velocity of light can be meas-

While the author of the accompanying article, a young English physicist, does not anywhere state that a varying velocity of light has been proved, and that the remaining problem is to determine its amount, it is feared that an occasional harried reader may run away with these beliefs. If questioned, many physicists might say something like this: "The chances are that there have been errors in some of the experiments, and that the velocity of light is a fixed constant. But, of course, we can't simply shut our eyes to the possibility that it is not fixed, even though this is more pleasant This article will provide background for accounts of future experiments -The Editor.

ured indirectly, with compact electrical apparatus, by finding the ratio between the electromagnetic and electrostatic system of units. This has been done with great accuracy on several occasions, and the results show no marked variation, the value of c in each case being close on 299,781 kilometers per second.

Other observers claim that, if light were slowing down or its frequency altering, such alterations could easily be detected by sensitive interferometers All such experiments to detect any alteration have given negative results.

What could possibly cause the variation in the measured velocity of light other than fundamental changes? The answer is nobody knows Apparatus more sensitive than that already used will have to be designed and constructed in order to investigate the matter De Bray has stressed the point that, in the case of the revolving mirror method. it is assumed that the laws of reflection of stationary mirrors still hold good, and that the laws of reflection of a pencil of light, from a real or virtual source which may have a transverse velocity approachmg that of light, are assumed to be the same as if the source were at rest. These assumptions, he suggests, may ultimately be shown to be inaccurate.

AT present, however, science stands at the crossroads. Experimental observations, on which the whole of science is said to rest, have presented it with a problem. Some changes have been detected in the measured velocity of light. One road leads to the type of solution involving extremely fundamental changes, the other to the theory that some new type of correction must be sought and applied. Both roads lead into unexplored territory. Which road will science follow? We can only watch and wait for the traffic lights to change.

Ships Can Carry Autogiros to Spot Submarines

MERCHANT essels need to be warmed of the proximity of submarrines if they are to elude or successfully fight them. Submarrines can be spotted most effectively from the sair, but ships cannot carry ordinary planes (plus catapults) and cannot stop, once a submarine is sighted, to host a plane shown date its water landing. Use of warships to convey liners or freighters subtracts striking power from the fleets themselves.

The autogiro, carried on individual ships and taking off from cleared present decks or built up ones, would largely solvo this problem, believe Scientific American editors. The idea, conceived in our offices over two years ago by F. D. McHugh, has been called eminently puetical by experts. Much experimentation is necessary, of rourse, but the 'giro has possibilities, as shown in our drawing. It can "jump off" 20 feet straight up and swing plant over to elear ships' super-structures. It can land with a run of about 10 feet. It can hover. It can carry machine guan to drive a submarine's gun c'ew below decks, and depth bombs to drop accurately while it hovers over the dark blob of as to drop accurately while it hovers over the dark blob of as submerged submarine. To the ship's gun crew, it can signal a sub's location and spot shell splashes by flares, Very pistol shots, or acrobatics. Finally, the autogiro can constantly patrol many miles around its mother ship.

DEEP PIERS BUILT IN STIFF TIDES

As the new bridge will look when completed. Note "lookout point"

New Suspension Bridge Near Tacoma . . . Two Deep-Water Piers . . . Enormous Tidal Current Pressure Forces Unique Anchored Caisson Construction

By CHARLES F. A. MANN

O UTSTANDING of all the large bridge projects under way as a result of the past year's Federal RFC-PWA program, is the Tacoma Narrows auspension bridge across the narrow channel lying on the westerly side of the Tacoma Peninsula, Tacoma, Washington.

Washington.

Two features of this bridge are of particular interest to engineers. One the fact that its central span of 2800 feet as the third largest such apan in the world, only those of the Gorge Washington Bridge in New York and the Golden Gate Bridge in San Francisco being longer. The other is the manner in which the engineers solved the problem of sinking two large piers to a depth of 175 and 200 feet respectively, against the enormous pressure of tidal currents double those at the Golden Gate

For more than 20 years, local people have dreamed of a huge suspension bridge across the Narrows to replace the ferries. Always two factors stymed the idea. One was the extreme depth of the

tidal current, the velocity of which, changing every six hours, reaches nearly nine knots. The second was the costliness of such a span in view of the semi-pioneer status of the section it would serve—a vast area larger than Switzerland, Holland, and Belgium combined.

A number of things brought the idea into a more favorable economic position in 1937. They were: the opening of the Olympic wonderland to tourists; the rapid growth of the pulp and paper industry; and the migration of hundreds of settlers from the midwest dustbowl to these cheap, well-watered landsall insuring greater travel. There was also the fact that the great Bremerton Navy Yard is rapidly becoming one of Uncle Sam's greatest naval bases, indicating a need for good highways and a fast Narrows crossing. Thus it was felt that a Federally supabout \$4.500,000 of its cost in 40 years. The chief task confronting the builders was that of sinking the caissons and constructing the piers. The cast spir of the Tacoma structure went down 200 feet. Tacoma structure went down 200 feet below water level and the west pier 175 feet, as contrasted to the deeper pier of the two at the Golden Gate Bridge, which went down only 100 feet. Hence it was decided to employ open-well type caissons with a wooden form built around the first part of each caisson to

perinit floating it into position and lining it up before it was lowered to the bottom. The two main caissons were 118 feet 11 inches long, and 65 feet 11 inches wide, with boat-bow points. These

ported project could easily liquidate

two una, were fabricated in Seattle and towed through the Lake Washington Ship Canal to the bridge site in Taroma

AFTER the sites for the two piers were located in the Narrows, 24 concrete anchor blocks, each weighing 600 tons, were dumped in a luge double circle around each per site These blocks were later anchored by cables to the floating seed easieson to hold them in place

against the terrific tidal strain. The

blocks were cast on huge barges and were corrugated in such a way that they

could grip the bottom mud. Having provided the anchorage, the two floating steel skeleton forms, which were covered with heavy timbering with caulked seams, were towed into place and anchored to the blocks by cable. These floating caison sections were spotted accurately by the use of shortwave radio and transits with telescopic

The caissons were partitioned into 24

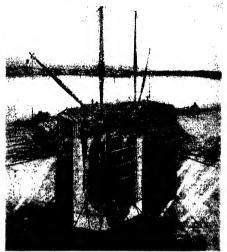

One of the monster 600-ton concrete anchors, sharply corrugated, that were cast on barges

feet 10 inches by 13 feet, all open at the bottom. Concrete was poured into the dividing walls of these sections to form a series of concrete and steel cells. As the added weight lowered the caissons a predetermined distance in the water, the anchor cables were adjusted to take up the slack, and the forms were raised so that another course of concrete might be poured. This was repeated over and over until the lower cdge of the caussons struck bottom Clam-shell buckets then excavated through these cells until the entire caussons dropped through the muck to hard gravel. Concrete plugs were then poured at both the top and the bottom, leaving the cells permanently flooded with salt water.

The Tacoma structure has a total length of 5939 feet. Towers cover an area 19 by 63 feet at the bottom and 13 by 52 feet at the top, and carry two cables 17¼ inches in diameter. Each tower weighs 1875 tons and the two cables 3817 tons. Each cable anchoring

An "anchor" makes a big splash when dumped overboard from a construction barge at a pier site

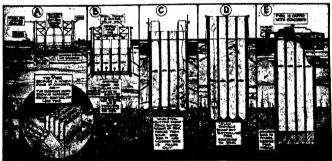

A caisson sinks lower in the water but is held rigidly by the anchors

consists of a steel and concrete mass of 25,000 cube vards weighing 52,000 tons, lodged in the hillsides above the Narrows. Each anchorage will form part of the main roadway. The bridge will have a 26-foot toadway and two five-foot sidewalks

The structure, which will be com-

pleted July 1, 1940, will reduce travel time from mainland to pennisula from 40 minutes to 10 and will be the best lighted structure of its kind. Towers and cables will be outlined in lights and the roadway equipped with sodiumvapor fog lights. Airplane beacons will be mounted atop the towers.

Step by step, a pier is constructed. Slack in anchor cables is taken up as caiseon sinks lower

Answer, Echo, Answer

E CHO, according to the Greek mythom was a mymph who pined away for love till only her voice remained. This charming legend makes pleasant folklore, but the science of sonics has given the echo a much firmer basis Although echoes still possess as poetic, eerie quality, we can now explain how they magnify sound, return some voices and ignore others, convert discords into music, carry whispers over long distances, and perform other weird feats which challenge the imagination.

Echoes are sometimes the radio stations of nature; without wires or sending-apparatus, they "step up" sound vibrations and hurl them enormous distances. Some years ago, 28 tons of dyna-

mate exploded in an Alpine railroad tunnol. The terrife blast was heard by Swiss peasants 20 miles away, the apparent him of the sound. Villages some 25 or 30 miles fartlier off heard nothing. Then, extraordinary news popped up 100 miles to the north, across the border in Germany, the noise of the explosion had been distinctly audible Had the sound of the blast "jumped" over a region 80 miles wide?

"Yes," said the Swiss Meteorological Institute. What had been heard in Germany was not the direct noise of the explosion, but an echo of it Every echo is,

you know. "mirrored" or reflected sound in this case sound waves, concentrated by the tunnel in which the explosion took place, had traveled upward, reached a heavy cloud fornation perhaps 50 miles to the north, which amplified and then reflected the waves to points more than 100 miles from their original source.

Everyone knows that curved or angled mirrors can play curious tricks with an image Sound-mirrors (another name for echoes) act similarly they "bounce" sound waves from surface to surface, often altering their volume, pitch, and number of repetitions. Probably no echo has ever achieved the record described by Mark Twain- "you could ntter a word and it would talk back at you for 15 minutes" But there is an echo in Oxfordshire, England, which repeats a pistol shot across a valley as many as 20 times the sound shuttling back and forth between two hills. Like some actors, this echo gives its best performance at night. There are Echoes that Magnify Sound and Others that Change Harsh Discords to Harmony . . . Echoes that Analyze Sound . . . Whispering Galleries

By ALBERT CARR

It has never been heard to score more than 17 repetitions by day, the differ ence is believed to be due to the more uniform temperature of the air at night A unique multiple echo exists at the Menni suggestion by Meles.

Menai suspension bridge, in Wales There, a hammer blow on the main pier is returned in a series of staccato reports from each of the clossbeams, all the way

POURCE SQUIND LETTENSE SQUIND SQUIND SQUIND OR ECHO

Reflected sound that is clear and definite is an echo

across the river—576 feet. To get an equivalent result with light, you would have to get up a long row of mirrors, equally spaced, and place an object in front of the row, at a wide angle Then, by standing in the right position, you could see an image of the object in each mirror all the way down the line.

miffor all the way down the line. Some echoes dusdam mere numerical glory and strive for a single brilliant performance. If, near a certain tomb on the Roman Campagna, you speak an entire hexaneter verse, the echo will construct the stripe of the stripe of the control of the stripe of the stripe of the stripe of the control of the stripe of the stripe of the control of the stripe of the stripe of control of the stripe of the stripe of the deserted city of Mandu, in Central India, there is a spot where you can utter a long, solid sentence, and have it voyage back presently to your ears, unbroken.

To produce one of these marathon echoes, the sound reflector must be so far away that you have time to speak for several seconds before the waves can make the journey to the reflecting surface and back again. Sound travels a mile in about five seconds; an echo which will repeat a five-second sentence therefore indicates a reflector half a mile away. Only extraordinarily clear acoustic conditions will permit the voice to carry so

far; hence the rarity of this type of echo.

As some curved mirrors magnify your image, some echoes magnify your voice.

Usually such "megaphone" echoes are heard in caves. At the famous quarried grotto known as the Ear of Dionysius, in Sicily, the crumpling of a piece of Cellophane will make you think a machine gun 14 at work. Why? Well, when echoes are thrown back simultaneously from many surfaces, their combined volume is louder than that of the original sound heard from a single direction. This phenomenon was once utilized by a troop of Mexican bandits when tranned by a superior force in a mountain pass Discovering that the crags around them multi-

plied both the volume and number of their voices, the bandits tried desperate expedient. Yelling and shooting, they dashed for freedom. The echoes, resounding from all sides, made the enemy believe that a regiment was charging down on them; they field and the little band escaped. This story, long current south of the Rio Grande, has furnished at least one movie episode for Hollywood.

Mark Twain, veteran echo-fancier, claimed he knew an echo which would speak only German. We may smile at the notion; but there are some echoes which are highly particular about the sounds they will do business with. One English echo has been called "The Suffragette," for, while it will respond to a woman's soprano voice, it pays no attention to a man's.

tion to a man's.

This sex-conscious echo does to sound what a colored mirror does to light. In a polished red vase, for example, you will notice that the reflection of blue objects

Direct sound of a dynamite explosion in the Alps, as the author describes, was heard in the area up to point A, but not in the zone of silence from A to B. The echo from heavy clouds, however, was heard in the distant area from B to C

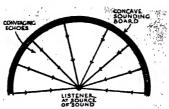

in it lose their color. The red light-rays of low frequency are reflected, while the high frequency blue rays are largely absorbed. The "selective" echo acts in the same way, throwing back some sound-waves in greater proportions than others

The chief factors in this phenomenon according to authorities on somes, are the size of the sound reflector, and the variation in the wavelengths which compose a complex sound like that of the human wors. Lord Rayleigh, the famed English physicist, showed that the intensity of sound scattered or reflected by an obstacte is

directly proportional to the size of the obstacle, and inversely proportional to the fourth power of the wavelength. (The same law, medentally, applies to the scattering of light, and is used to explain the blueness of the sky)

When, according to this law, sound waves of various lengths traveling the same plane encounter a small obstacle, the longer waves tend to continue beyond it, much as large water waves pass around a rock and close in again on the other side, without substantial interruption The shorter sound waves, on the other hand, are scattered, somewhat like small water waves encountering the same rock. Consequently, when the sound reflector is small, the chances of the scattering and reflection of short sound waves are much better than those of long sound waves. Since the shorter waves represent the higher tones of sound, it is these tones which we hear most loudly when a small, distant reflector happens to produce an echo.

Certain selective or "harmonic" echoes have the curious trick of raising the pitch of sounds. At the Gap of Dunloe, in the lakes of Killarney, it is said that

How echoes are magnified The sound waves, having traveled out from the source in all directions, smultaneously converge back on the shouter from all directions, causing more intense vibration of the eardrum than was made by the original sound. He virtually shouts mouth squants ear

the glass, of a long dead musician will accompany whover plays a high there. It is perfectly true that the echo of each note comes back an octave higher, and that it provides a harmonium accompaniment for a simple bugle call. The principle is that of the selective echo, a small obstacle, such as a clump of trees, will return the first harmonic wavelengths, or octave, of a fundamental tone more efficiently than the tone useff.

Everyone has observed how a prism or spectroscope grating breaks up sunlight into its component colors. Here and there an cho will do the same thing to sound, producing a "sound spectrum." At Bighorn Canyon, in southern Montana, the rushing roar of the river is sometimes echoed from a certain section of the cliffs in a howl like that of a police-car siren, beginning on a high note and sweeping down into the bass clef. Years ago Indians in the neighborhood used to shun the spot for fear of "evil spirits" Today we know that the various wavelengths in the sound of the river are reflected by different parts of the jagged cliff, reaching the ear separately, instead of all at once If the observer takes an

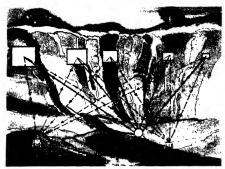

other position, he can cause the order of the sounds to be reversed, so that the echo begins with the deep tones, and rises to the treble Physicists say of echoes of this type that they "analyze" sound

I remember standing nearbagle Harlor, on the wooded shore of Lake Superior, and hearing what sounded like a celestial hymn, played in alow time by some mysterious organist For a while I thought I had suffered a halliemiation. But similar experiences of others in that region show that what I heard was the roise of the waves of the lake on a pebanalyzed and echoed har-

bly beach, analyzed and echoed harmonically by the forest behind

The musical or ho is certainly the most charming of all the numerous excho family. Its principle weems to be to repay wil with good On Saddleback Momnatan in Maine, the most hideous discords—such as an Indian war-whop—are returned as a delightful, soft, musical note Scale reloses are generally found only where there are symmetrical rows of trees which "cut out" or abort certain sound frequencies, and reflect the others in a harmone relationship.

Perhaps the most dramatic of all echoes are those in which the sound is reflected from deeply curved surfaces. The whispering galleries of the world are all of this type One of the best known is under the great dome of St. Paul's Cathedral in Loudon. There a whisper will creep across from one side of the dome to the other, to be picked up with astonishing distinctness on the opposite side, 102 feet away. The Ear of Dionysius, already mentioned, is one of the finest of all whispering galleries. At its top is a small passageway where the visitor can distinctly hear the breathing

An abstract diagram of the action of an "analyzing" echo. Large reflecting areas throw back more of the deeper sounds; small ones more of higher sounds. Owing to differing total path lengths these "analyzed" echoes arrive in succeesion, but from high to low for one listener, low to high for the other

of a man on the floor, 120 feet below. The tyrant, Dianysius of Syracuse, conceved the notion of imprisoning political enemies in the Ear, and by listening at the top, was able to overhear their whispered plots and secrets.

How is it that a whisper which cannot be heard for 20 feet under normal conditions will carry 10 times as far in a whispering gallery? The explanation hes in the fact that the sound is "slanted" off the smooth inner surface of the round done again and again, traveling in a series of arcs. A helpful analogy is to magine a billiard ball with "forward spul" as it strikes a cushion at an acute angle. Under the right conditions the ball instead of heing slowed down, 'picks up.' Similarly, the volume of sound "picks up.' Similarly, the volume of sound "picks up.' in whispering galleries as it travels over the curved reflector.

E CHOES have been used as a method of torture. In the Cave of the Snake. in the wrinkled and lonely hills of the Kamun Range of India, the least sound is repeated in a low rushing murmur that seems to pervade the doomed chamber A torture-loving Raigh once conceived the notion of putting his victims. one at a time, in the pitch blackness of the cave with no company but that of a deadly black cobra. There was no way of telling how soon the cobra would encounter its destined victim, and strike But every time it moved or lussed the slithering sound would seem to come from all directions. Under the unbearable suspense the prisoner would die a thousand deaths before the fatal moment came

However, the Rajah felt that in not overhearing the sufferer's torture he was

missing the best part of the fun. So he had a small opening made in the sealed entrance. And—as was to be hoped while he sat with his ear to this opening, the snake erawled up and bit him.

The best known of America's whispering galleries is in the Capitol at Washington, in Statuary Hall, where if you stand in the proper spot you can communicate by whispers with a friend 50 feet away.

Most land echoes seem to have no other purpose than to entertain the currous. But at sea, echoes work for their living, measuring ocean-depths for navgators. The echo depth-finder used by the United States Coast and Geodetic Survey in charing the bottom of the ocean, and earned by particelly all important vessels, enables a shy running at full speed to obtain four soundings a second in depths of 600 feet. 'Sound, be it noted, travels approximately five times as fast in water as in air.

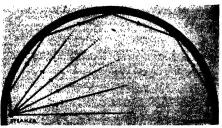

The principle of the instrument is simple enough. Sound waves, produced under water, speed to the ocean bottom, and are reflected upward. An electrical device measures the elapsed sound and the return of the echo, and this time interval is recorded in terms of depth. In war time these depthinders have helped ships to detect the presence of submarines by recording the sound whost the results.

The story goes that many years ago, in the cathedral at Grigenti in Sielly, a gentleman was kneeling alone near the high altar, when he suddenly heard a distinct whisper have sinued. "Bless me, father, I have sinued."

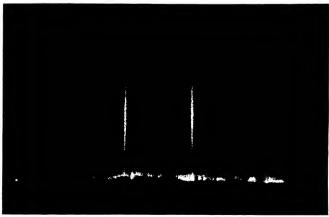

Startled, he looked around. There was no one near him. The whispered confession continued. Amazed, he concluded that it could only come from a confessional booth over 100 feet away. He approached the hooth, but at one the whisper ceased. Returning to the original spot, however, the heard the words as clearly as if they were being muimured into his ear.

Unfortunately, he was not content with the discovery of an acoustic plic nomenon. Delighted at the prospect of rare entertainment, he invited some of his friends to join him nearwidropping on the confessions of their neighbors. But, appropriately enough, in the very first confession, he heard the sound of his own wife's voice admitting sins no husband cares in have on his wife's conscience.

A MONG rchoes as among people, there is infinite diversity. One finds on only easygoing, good-natured schoes, but grumblers, loud-mouthed bores, wiserackers, show-offs, temperamental artists, and a few hard workers. But Little Sir Echo always has one advantage over merely human sound-makers. No one expects him to be original

Spectacular pillar halos at Wilbur, Washington, photographed at 12:15 A. M. by S. B. Breed. Five-minute exposure at //3.5

PILLAR HALOS

XCITEMENT Caused by Freakish Lights" was a headline in the Wilbur (Washington) Register. "Last Thursday night," the news item beneath it stated, "those of our citizens who were awake witnessed a display of freakish lighting effects that is seldom equalled for beauty. From every outdoor light-street lights, electric signs, and automobile headlights-there arose perpendicularly a shaft of light high into the air. Within these ghost-like beams there flickered and danced millions of particles of frost." On this occasion one Scientific American reader. S. B. Breed, of Wilbur, thought to photograph the odd phenomenon and sent this magazine the illustration shown above, with a request for a scientific explanation.

When readers send this magazine decriptions of odd meteorological or atmospheric phonomena for explanation, the editors turn to W. J Humphreys' "Physics of the Air," a standard advanced reference work about this particular corner of science; often also, as in this case, to the author himself, Dr. Humphreys, because his lifetime work as Professor of Meteorological Physics at the United States Weather Bureau in Washington, has brought to his attention myriads of meteorological oddities. "The photograph," he replied, "is of pillar halos and is the best I have seen of that phenomenon Pillar halos," he continued, "are produced by reflection from the upper and under ades of tabuses "in extension of his comments wise." In extension of his comments wise." In extension of his comments the Monthly Weather Review of the United States Weather Bureau, by B. W. Currie, Professor of Physics at the United States whether Bureau, by B. W. Currie, Professor of Physics at the United States whether Bureau, by B. W. Currie, Professor of Physics at the United States whether Bureau, by B. W. Currie, Professor of Physics at the United States whether Bureau, by B. W. Currie, Professor of Physics at the United States of the United States and the United States of
"The color of the light from the pillars, and its state of pulsarization, show that they are caused by reflection. The color of each pillar is exactly the same as that of the light below it, the red pillars from neon electric aigns are particularly noticeable. The apparent height of a pillar increases with the intensity of the light source. Calculations based on known distances to light sources and the measured sizes of the corresponding pillars on photographs often give heights in excess of 1100 feet.

"Two kinds of crystals—thin hexagonal plates and thin broken fragments of snowfikkes—cause the pillars. Only the first kind is found on calm nights when the most brilliant displays occur. Both kinds of crystals may be found when the pillars are seen on windy nights.

"Wand velocities less than eight miles per hour seen seentual to the formation of bright pillars. If wow is falling, the pillars can be seen only if the wind is strong enough to break the snowflakes Temperature conditions show no untormity, partly because the cryatis are formed at higher levels and then fall to the surface."

Sometimes pillar halos are similarly seen above the sun or, if the sun is high, below it as well.

Related directly to pillar halos are several phenomena which do not at all resemble them in shape: certain arcs and circles, seen surrounding the sun. often in elaborate complexes like schoolroom exercises in geometry. All have scientific names such as perhelic arcs and circles, anthelic arcs and heliac arcs. But the plot rapidly thickens, for a part of these are caused by reflection, and, to complicate the complexity, there is a third class of ring phenomena due to diffraction: coronas, solar or lunar. Halos are red inside, blue outside, coronas the reverse. Writers often confuse the three classes and who can blame them? Short of close study and perfect memory it is safest not to leave the vicinity of a textbook.

MONTHLY DIGEST

BIKE TIRES TESTED

TIKE its big brother, the automobile tire, the bicycle tire now undergoes actual road tests in addition to laboratory check-

ups to insure serviceability. On a unique machine invented by engineers of the Fisk Tire Company, four bike tires can be tested at one time by means of a trailer arrangement hooked to the rear of an automobile.

The four tires run simultaneously, each under an individual load of 125 pounds. The

Heavily loaded tires under test

automobile pulls them at 25 miles per hour, rain or shine, to simulate actual service conditions

According to A E Benson, Fisk product development manager, the tests provide the following information Behavior of tire on different types of rims, resistance of carcass to fatigue at different inflation pressures. stability of beads in maintaining a true running tire, resistance of tire to rim cutting, quality of rim strip in resisting indentation of spoke heads; quality of tube in maintenance of air pressure and freedom from excessive growth, and quality of tread stock resistance to wear

Indoor tests on another machine provide a double check on the same conditions

PERFECTED "RUBBER Lung"

SHORT time ago newspapers carried A SHORT time ago newspapers carried the story of the first use of an artificial lung on a mother during childbirth. The mother was afflicted with paralysis a short time before the child was to be born and had been kept in an iron lung. Delivery was, of course, impossible while she re-mained in this machine, so a smaller, newly Conducted by F. D. McHUGH

Contributing Editor

ALEXANDER KLEMIN In charge, Daniel Guggenheim School of Aeronautics, New York University

developed lung was borrowed from the family of a paralysis patient, Fred Snite The delivery was successful

The small lung which served in this case was one which was discussed in Scientific American about two years ago, and was de veloped in part by the General Tire and Rubber Company In an accompanying illustration will be seen the latest perfected model of this lung, which not only provides the patient with a regular rhythmical supply of air but leaves the limbs free for any neces sary manipulation or massaging by nurses It will be noted that an additional feature of this is the transparent plastic cover through which the patient's chest action may be observed. This device, when strapped over the chest, is sealed around the edges by sponge

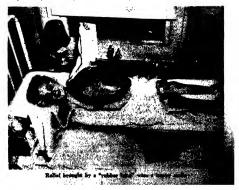

rubber. This emergency lung, which is called the "General-Collins," is easily transportable,

by a hand pump if electricity is not available, and is so mexpensive that it might be carried as regular equipment in even the smallest hospitals, in police emergency squad cars, fire-fighting units, and by first-aid organizations of all kinds. It has been designed in four sizes to care for patients from infants to large adults

BACTERIA CAUSE KEROSENE EXPLOSION

BRITISH authorities have for months been puzzled by mysterious explosions in gasoline storage tanks holding their war time fuel Sabotage was suspected but un proved, for the terrific explosions brought complete catastrophe. Finally a kerosene tank blew up and, after the explosion, bubbles of gas were noticed rising from the layer of water at the tank's bottom on which the kerosene had been floating

The government's expert on the generation of gases by bacteria, Dr A. C. Thaysen, examined some of the water and sediment It was found that they contained a new kind of bacteria which can live in kerosene and fernient it into 10 percent ethane and 90 percent methane It was undoubtedly

these explosive gases, generated by the bacteria, which caused the explosion. While Dr. Thaysen has not solved the puzzle of the gasoline explosions, he is virtually cer tain that a similar action was responsible Science Service.

BLOOD

THE Japanese are said to have added to the soldier's name on his identification tag, which he wears around his neck, one of the letters: O, A, B, or AB. Precious time is thus saved if the soldier is wounded and needs a blood transfusion, for the letters indicate his blood type, previously determined

DE-ENAMELING LIGHT SHEETS

TO its line of sand-blast guns, Michiana Products Corporation has added a new model which is now being used by makers of vitreous enamel products, such as stoves, refrigerators, cabinets, and sinks, for deenameling defective sheets or parts which are ordinarily a total loss. This new gun has five outlet nozzles or orifices through which the sand is discharged with a brush like action, cleaning without peening or distorting sheets 19-gage and lighter. Be-

Sand hlasting for reclamation

aides de-enameling, the makers recommend this type gun for cleaning wood, stone, and other materials, the surfaces of which might be damaged by a harsher, single nozzle

100-MILE-AN-HOUR

ANTI-AIRCBAFT COMBAT CAR

E QUIPPED with three machine guns and a cannon, capable of traveling more

than 100 miles per hour, built of .50-caliber bullet-proof armor plate and glass, mounted on bullet proof tires, able to climb grades of 50 percent inclination and travel through mud, sand, and broken ground, having a cruising range of 225 miles at 70 miles per hour, as easy to drive as a motor car -- that, in substance, is the newest type of anti-aircraft combat car.

This new mobile unit is a powerful arm of defense against lowflying aircraft on ground strafing missions. Its armament, speed, maneuverability, and bullet-proof construction make it always ready for in-

stant use Designed by Preston Tucker of Tucker Manufacturing Company, this "tank" was made possible by use of the most modern steel construction process—are welding Arcwelded construction actually makes the ma-chine hullet-proof. Welding does away with bolts and rivets which hecome worse than projectiles when driven into the tank by heavy gun fire. While eliminating this hazard, the arc welds are themselves bullet-Welding on the Tucker Tank was done with electrodes and arc welders manufactured by The Lincoln Electric Company.

This tank is equipped with one 37mm full-automatic cannon firing at a rate of 120 shots per minute, and three .30-caliber mashots per minute, and three 30-caliber ma-chine guns. The turret rotates freely, giving complete firing range, and all glass is 2½ inches thick and so placed as to give full

stability.
A most of TIA miles an hour is possible
that the appropriate motor belong a seron-

speed transmission. In addition, the unit has a 108-inch wheel base and a standard racing-car arrangement in springs and chassis. Tires are apparently sponge rubber 'airless" type.

Radio equipment and compass are con tained in the interior which is air conditioned for comfort

TREES

MORE than 6 mill on trees were planted in windbreaks and shelterbelts last year in a total of 30 states.

ERSATZ RUBBER

WITH synthetic materials in many instances replacing more expensive and less satisfactory natural products, the question is often raised as to why substi

tute rubber remains so high in price
Using the production of Buna, Gernany's substitute rubber, as an example. Plastics (London) points out that the process is so complicated that certain basic costs cannot be decreased The works plant is costly, maintenance is much higher than in ordinary plants, the highly inflammable materials need special precautions, continu ous testing and research are expensive, but necessary, adminels. But the mein reason for ligh cost is the fact that there are so many intermediate processes The first step is the manufacture of car

bide from lime and coke in an electric furnace using 10,000 volts. This needs a sizable power station to produce the necessary 100 to 200 tons of carbide a day. The carbide is then treated with water to produce acetylene The acetylene is trans formed by catalysis and hydrogenation into the chemical butylene glycol. The yield of these two processes is only 35 percent The yield of the theoretical. Two more steps, another transformation, and a polymerization, yield the rubber substitute. The polymerizing agent is metallic sodium, difficult to handle.

To make one ton of rubber, four tons

of acetylene are required. And to make this quantity of acetylene, at least ten tons of carbide are needed.

It is interesting to note that, should the cult of self-audicioncy die out, the production would decrease and the price would increase. And, as in the United States, the use of the synthetic material would be restricted to its proper and special uses hased on its inherent advantages over the natural material.

AERO-BIOLOGY

HAY fever victims will find aviation an aid in their woes if the researches "aero-biologist" C. C. Durham, of the Abbott Laboratories, are successful. Dr. Durham is a botanist who investigates the distribution of pollen with the aid of a microscope and a kit of Vaseline-covered slides The slides are fitted into a "skyhook," and flight investigations of the upper atmosphere have been made with the aid of United Air Lines, Pan-American Airways, and Pennsylvania Central Airlines. Above 6000 feet there is little ragweed or other irritating pollen to be found. Even at ground levels in the Pacific Northwest the air is virtually free of any hay-fever-causing pollens. Flying in the Yankee Clipper, Dr. Durham's slides show no spores farther from land than 275 miles Sufferers from hav fever had better spend their lives flying. particularly flying over the Atlantic ! -- A.K.

THE ASBOTH HELICOPTER

W/E have described at some length in these columns the remarkable characteristics of the Focke helicopter, which is of the type where airscrews, turning in contrary directions, are mounted on each side of the fuselage Now, thanks to the Aeroplane, (London) we are able to give a description of the latest Asboth design. which is apparently to be built in England. The Asboth machine, illustrated in the drawings, is known as the A H. X With a Cipsy engine of 200 horsepower, a gross weight of 2148 pounds, and a disposable load of 385 pounds, the A. H. X. is estimated as having the following performance Maximum horizontal speed, 107 miles per hour, ceiling, 11,500 feet; initial rate of climb, 1760 feet per minute, lift, 3260 pounds, giving an excess of lift over weight of 1100 pounds Speed of vertical descent

End view drawing of the Asboth helicopter. Wheels retract into wing

with the blades auto-rotating is somewhat high, in the neighborhood of 40 feet a second, although the vertical descent speed can be reduced to 16 feet a second by gliding the machine down like an airplane or an auto-

The drawings give only a hint of actual construction Incidence of the blades is varied from hub to tip. If the engine fails, the incidence is automatically changed, so that auto-rotation follows. Without automatic auto-rotation, a helicopter would be a dangerous vehicle when the engine quits.

The blades are set rigidly on the hinge and do not flap. There is a "four function" hub. The hub ellows the six-recws to be tilted forward to give forward thrust, and permits auto-rotation as previously stated. Control surfaces are carried in the faired heam, which is really a small wing The landing gear retracts into the wing, and

the now commonly accepted tricycle landing gear is embodied in the design. We admit that this is a sketchy description and hope that more details will shortly be forthcoming. In the present state of the art it is highly desirable that both the superimposed aurscrew type of helicopter and the outboard airscrew type should be developed in competition with one another—4. K.

THE FUTURE OF

DR 11 E WIMPERIS, former Director of Research of the British Air Min istry, is a man of vast experience in aeronautical matters. His recent address before the British Association for the Advancement of Science, on the future of flying, may therefore be regarded as an authoritative view of thinas to come

Speaking of materials, Dr Wimperspoints out the virtue of the high-strength aluminum alloys so generally employed to day in the building of aircraft. But aluminum alloy means hundreds of thousands of rivets in a large airplane. Therefore, plastic materials, while no better from a strength point of view, may mean real improvement in production methods.

What is the position regarding speed? Physiologically there is no limit to speed, provided only that high speed is not associated with rapid maneuer Does not the carth sipn around at vast speed without incommoding us in the least? But there are two probable limits to sirplane speed For commercial aircraft this should be around 250 miles per hour, simply because the forecommercial aircraft this should be revoluted to the between 500 and 600 miles an hour, because of the "compressibility burble" which occurs near the speed of sound, and which even the best arfolia cannot postpone indefinitely. With compressibility burble, the drag or air resistance increases enor-

What of the engine? Three thousand horsepower in a single unit is n sight. One great improvement which has entered British but not American practice is the sleere-valve to replace the conventional oppoper valve. The alever-valve is no novelty (if has been used in the automobile) and it has only half the component parts of the ordinary popper valve, permits inlet and configuration of the product of the configuration of the con

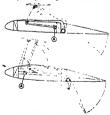

the cooling air to produce thrust. In such a case, instead of drag, the cooling system may actually produce forward thrust!

may actually produce to twater threat:
Special wings may be developed which
will keep the flow over the surface of the
mittel laminar instead of tradeless. With
mittel laminar instead of the mittel with
mittel laminar instead of the mittel with
mittel laminar instead of the mittel with
then the position of the propeller must be
changed. It is not the slightest use to
design "laminar flow" wings if the slipstream of the propeller placed at the leading
edge of the wing upsets the air flow. Dr.
Wimperis therefore argues in favor of the
pusher propeller introduces
problems of its own, such as moving back
of the engine and change in tirm or balance
of the aircraft; the ner easty of a long shaft
drive from the engine, with attendant wibration troubles; and proximity of the propeller
laspitation to the tail surfaces. Nevertheless, the combination of "laminar flow"
wings with pusher propellers offers an

The higher the wing loading, the greater the speed and carrying capacity. The Wright brothers carried a loading of 1½ pounds per square foot of wing area. Dr Wimperia speaks of a stall append of 100 miles per hour, and wing loadings of 40 pounds per square foot Particularly in transallantic Rying we may expect tre mendous wing loadings to permit non-stop mendous wing loadings to permit non-stop hours are the properties of
These semi-popular, semi-technical views of a well-informed man are helpful to both layman and technician —A K

PUSHING THE FLAP

THE flap has proved itself highly useful In airplane design, but aeronautical engineers are never satisfied. Therefore, double-flaps, designed by H B. Irving, are being tested in England. Our own N.A.C.A. is experimenting with a Venetian-blind type of flap with promising aerodynamic results

Two types of the Pidcock combination "slat" and flap for planes

to compensate for mechanical complexity. The Aeroplane (London) describes briefly the Pidocok combination of forward "dair" and flap illustrated in two of our drawings. In the Pidocok combination, the effect of the flap in increasing the lift capacity is combined with the lift increase effect of the slat which emerges from the surface of the

wing, and gives a biplane effect. The inclination of the forward slat can be adjusted by the eccentric at the points A on the drawings. There is another reason why the combination of slat and flap is worth considering: The depression of the flap tends to nose the sirplane down; such a tendency would be counteracted by the lift force forward of the slatt—4 K.

CONTRAST IN TRAINING

PLANES

TWO of our photographs show a definite contrast in modern training planes. The Stearman PT-13A Army primary transing plane is a biplane, powered with an engine of more than 200 horsepower, with a top speed of around 150 miles per hour. The Stearman is a rugged biplane, of short here is a regardeness available for the most violent stutting. The cockpits are open so to give the "freed of the ari" to the pilot on the pilot of the most violent stutting.

The Porterfield Model 50 is a decided contast it carrier only a 50-horspower Contamental engine, of the four cylinder opposed type, and the open cockput can be converted into a confortable cabin with plenty of vision. The Porterfield Trainer has been apecually designed for the thousands of students who will undertake C. A A flight training all over the country the small shape now being used for such training—the Porterfield, Aeronca, and so on—are remarkably economical, easily

ers across the North Atlantic straight from factories in Ganada is much more practical. In fact, the Albes may expect a great deal of help in serial warfare from Ganada. The Society of British Atroraft Constructors tells us in a new letter that II major Canadian engeneering firms are handling aircraft production work, and that the pulse of production us quickening every week. The network of factories is spread throughout the Dominion, with torpedo planes being built as far west as Vancouver. Our northern neighbor has a great opportunity in military avanton—JK avanto

IS THE WESTWALL. INVINCIBLE?

IF Germany's bristling Westwall proves invincible to attack in the present war, it will be the first great wall in history that has ever completely justified the trust put in it, says Science Senice

China's Great Wall, a berrier 1500 milelong, 15 to 30 feet high and reinforced by thousands of towers, was built to shut out barbarrans who kept swooping down from the north Costing thousands of Chineslives in the construction, one flippant crack later summed up its worth. "The Chinese nevey got over it but the Tartars did"

Two modern training planes with desirable characteristics. Below The Porterfield Trainer, and, right, a Steaman primary trainer

Minich began working with this product

and developed a machine with which he

does things to it. From Pliofilm, treated

and turned into Tensolite, is made a dental

floss, bristles of many kinds, tape in numerous colors, and, even a fiber as fine as

cocoon silk. One of the bristles has an

abrasive core, so that when made into

brushes it will abrade a surface at the same

time that it polishes. Sheets have been

made that are, in the commercial grade,

.0002 of an inch thick, but experimentally

they have been made to a thickness of 00008

of an inch. This last sheet puts the word

ın sır.

gossamer" to shame, for it actually floats

Tensolite laminations in different colors

are made into attractive striped tapes End-

less belts may be made from it; or colorful

sheets for such things as raincoats, each side

of a different color. Air-like filaments have

made very satisfactory fishing lines and lead-

ers, badminton and tennis racket strings, yarns and threads and tapes have been woven into cloth, belts, trimmings, and baskets

All Tensolite products are proof against water, oil, grasse, acid, alkah, perspiration, mold, and vermin. They stand all normal temperatures, are non-explosive, and can be printed They have long shelf life and may be cleaned with soap and water or may he dry cleaned. They must not be rorned, but can be pressed readily with weights. While the original Plotfin supports slow combustion, Tensolite contracts so rapidly in the presence of fiame that it actually runs away from the flame statully runs away from the flame.

handled, of slow landing speed due to their low wing loading (6.5 pounds per quare foot on the Porterfield), and safe in students' hands.

Neither the operators who give the in struction nor the students who undertake it have any reason to complain of the equiment at their diposal. Main data on the Porterfield Transer are: High speed with open cockpil, 95 miles per hou; gross weight 1100 pounds; useful load 455 pounds; length 22 feet of inches; wing span, 34 feet 9 inches; wing area 168.8 square feet. The students for whom Uncle Sam is providing flying training are to be envised—4. K.

CANADA TO THE RESCUE

THERE was a beautiful ides propounded in the press that British and French warplanes could fly to Poland's aid and shuttle back and forth, dropping deadly bombs on the German forces. The great distances involved and the destruction of the Polish aerodromes rendered the plan unfeasible. But the scheme of flying bomb-

Iladrian's Wall, which crossed Britain from coast to coast, fortified Roman Britain against invasion from tribes of the north Although the last word in 2nd Century A.D. multary construction, the strongly fortified barrier was atormed and broken during more than one conflict.

In Germany itself, Rome's old Limes Line that marked the limit of conquest was not particularly heavy, but the Romans thought it adequate when they had backed it by block-houses and manned it for defense. When internal troubles weakened the empire, however, Franks and other tribes ran over this great wall and swept on in triumph into Gaul

TRULY VERSATILE

A NUMBER of amazing products of Tensolite, were shown us recently by Henry D. Minich. Rubber hydrochloride has been known or a number of years and was introduced in a stabilized form by the Goodyear Tirq and Rubber Company in 1934 under the now well-known name Pliofilm. Mr

TAR

THE average smoker lines his lungs with 8 quarts of tobacco tar in a period of ten years, according to the estimate of Dr. Angel H. Roffo. of Buenos Aires. Argentins.

SULFAMIC ACID

RECENT development of a practical process for commercial-scale manufacture of sulfame axid (HSO,NHs) has stimulated a wide interest in this new mudustrial chemical. According to Industrial and Engineering Chemistry, a number of industrial uses based on the unique chemical and physical properties of the

With simple equipment amateurs can make sound-on-disk talkies

acid have already been developed. One such use is based on the rapid reaction of sulfame acid with mirities to yield nitrogen and sulfure acid.

A novel industrial application of this reaction is its use for the necessary removal of excess nitrite following one of the steparce which is command used for such pure. Sulfamis acid is two to six times more effective than area which is commonly used for such purposes. Higher concentrations of intite may be in most cases may be shortened from a period of hours to a period of a few minutes Cleaner shades of color and greater uniformity are thus made possible.

FLUORINE FILTERS

In some sections of the country, mottled teeth have become a serious problem because of the fluorine in drinking water. This cause of insightly teeth, discovered only a few year, ago, has set many research scientists working on ways to chimiate it Dr. H. V. Smith of the University of Arizona. College of Agriculture, reports some success in this direction.

Or Smith has invented a small filter cartridge, adaptable to drinking fountains, and made of home. Another type is larger and suitable for treating the water supply of schools or homes. An electric alarm is set off when the filter in the latter type has absorbed all the fluorine it can and hence needs replacement

The bone filter is made by treating animal bone with caustic soda, then washing it with water and finally neutralizing it with a dilute acid

ARC-WELDED STEEL RIVER TUNNEL

CHICAGO'S new river tunnel, a double tube of steel, 200 feet long, 40 feet wide, and 25 feet high, which is to carry State Street subway cars under the Chicago River, is the most intricate job in Chicago's new subway system. The guant tube will rest in a trench dredged to a 30-foot depth below the river bottom and will be sealed at both.

ends, towed 15 miles to its site and sunk by pouring concrete on its top

Different from ordinary procedure in tun nel work, (which involves boring beneath the river bottom), anking the section as unit minimizes the depth of earth covering over it—five feet as against 15 with conventional practice. The shallower depth has the added advantage of providing a slighter grade in and out of the tube than would be the case otherwise

How Effective Is Aluminum Foil. Insulation?

R ECENT investigation of heat transfer sheet of alumnium foil placed midway in a horizontal air space with the heat flowing downward is equivalent to approximately three inches of corkboard in insulating value. With three layers of foil in the same space, the heat transmission is reduced to

almost half that obtained with one layer.

The investigation also showed that the eye, while a good judge of reflectivity, cannot evaluate aluminum as an insulator. Surface films formed by exposure to laboratory tumes and dust, salt spray, and by normal use as a house insulator are readily visible to the eye, but decrease the insulating value very little.

AMATEUR SOUND MOVIES

S QUND equipment for amateur move baddiets, available for some years, has made use of the regular film sound track which, of course, necessitates the use of photoe-lecture cells and survivary quapment. Now, for the first time, anateur movies quapment. Now, for the first time, anateur movies quapment disalgage, many, and sound offects—all reproduced as perfectly as sound on film but the use of a phonograph dask in the Svacrosound System, a product of Presto Recording Corporation

The entire soul recording and repretable the soul recording and repreciation of the soul recording and an angle carrying case that weighs less than \$50 pounds. It can readily be carried by one man. The cost of the equipment is about 1/10th as much as the lowest priced sound on-film equipment. The cost of the sound coordings themselves averages about 20 cents a minute of running time, or one doil lar for a five-minute reel. The weight-rounds tion is automatic, requiring no supervision or adjustment once the preture is started

The sound recording and reproducing system can be added to any stendard make of silent 8 or 16mm camera and projector 11 consists of a portable sound recorder, an electric motor drive for the camera, and a small attachment for the projector The latter units can be installed for a few dol lars and they can be quickly detached if desired to make silent filias.

SLOW FUSE

ELECTRIC motors, coils, solenoids, mag nets, and relays often have overloads which are not necessarily harmful but which, nevertheless, blow the ordinary type

GET 1940's BIGGEST PACKAGE OF PHOTOGRAPHIC THRILLS At This Special Bargain Price!

Reserve Your U. S. CAMERA ANNUAL NOW! THE BOOK EVERY CAMERA WORKER NEEDS ... MORE EXCITING AND HELPUL THAN EVER.

To photographer, U. S. CAMERA ANNUAL is the one "must" book of the year. Each Fall the fifteen to twenty thousand of the year's best prints made by American photographer—both amester and professional, known and unknown. From this mountain of prints, they select the cream of the year's copy—which forms the man part of U. S. Camera Annual.

In former years, the collection of the best work of American photographer—reproduced by fine gravite printing—was enough to vin acclaim from hundreds of book reviewers and act critical in provided impiration and guidance for thousands of photographs But, never content with pest achievaments, Editor T. J. Malonay this year saided marry new features to increase the value.

Finer Printing, Better Binding

First is an improvement in reproduction Each photograph in the book is reproduced in letter from printing of photographs By the use of No. I Gloss Ensemel paper and 130-line halfone, more datall, brilliance and tonal variations of the corginal salon prints are preserved then possible by any other printing method.

cases, ortisance and tones variations of the original salon prints are preserved then possible by any other printing method.

Second new feature is an improved binding that makes U. S. Camera a more beautiful, lasting addition to your library than aver before—and at no change in price!

More Articles, More Inspiration

Third big feature is its editorial contants this year it is more than a salon-in-book-form It bas more fine pictures than ever before, but in addition it has more written and edite then ever before! It is a book to read and study, as well as book to fook at

SUMMARY OF CONTENTS

Here is a partial list of features of U. S. Camera

Over 250 pages containing basutiful reproductions of the 300 greatest pictures of the year.

Edward Staichan, sole judge, also contributes a simulating commentary on Photography today.

Edward Weston's Guggenheim Portfono: a twenty-four page section entirely devoted to Bdward Weston's famous Californie photographs. Mr. Weston also writes a fascinating description of how this monumental work was dona, the resoning back of it, and the problems involved!

Hundred Year's of Photography by Elizabeth

tographic subjects traces the contributions of this exciting art—not in tarms of its early phases but its place in the contemporary American scans

tte place in the contemporary Amarican scana

Bigger Color Section Better than ever this
year because of the improvement in color tech
inqua. Bigger, too; full page reproductions from
fine process plates, of the work of America's lead
ing color photographers.

Greatly Enlarged Date Section Still more complete date on exactly how each picture was made with all equipment listed, and this year begraph red and personal date on the photographer himself!

Spacial Features 1939's outstanding newspictures Groupings of unique teature photo graphs contrasts and humor shots breathtaking serial panorames amazing ail antific photographs documentary pictures portests and percorisis, nudes and illustrations that axexis, entertain and stimulating

U. S. CAMERA MAGAZINE

A SOLID YEAR OF PHOTOGRAPHIC INSPIRATION AND INSTRUCTION AT VERY LOW COST.

Would you like Ansal Adams to tall you how to photograph Architectura, Illustrating his points with a serias of magnificent prints of a California ranch-bouse?

Would you like to hear about Paul Strend's work and photographic philosophy from Elizabeth McCauslend?

Would you like to see a collection of Ton: rissell's best work, and have Frank Crownto osald tell you bow and why she does it?

Would you like to see the scores of prize-win ning pictures from the many thousands entered in the U.S. Camera Magazine Competition?

Would you like to know how Barbers Morgan photographs the modern dence? How Elliot Elisofon does his documentary pictures?

Art Center School of Los Angeles works?

Would you like to know more shout the work of Lessren, Hiller, Affred Steightts, Martin Munkacs, Valentino Serra, Elliot Portar, Margaret Bourks White, and dozans of others?

Many Exciting Features

These are just a few of the features in coming issues of U S Camera Maganne—America's continuat and most excining photographs, publication As it enters its second year, now firmly similarities to the front rank, this embirous maganne intends to make asch issue bigger, more instructive and simulating that pravious issues

Giving Readers What They Want

In the next six big issues of U S Camers you will see a more thrilling collection of analysical stricks, simulating commentaries on photography's piece in the sun, pretaze—sacrifing,—than you've aver rand or rean before Thing,—than you've aver rand or rean before Thing by and shout knowns and unknowns, amateurs and pros, but they'll all he good.

So make sure you won't muse a single one of these next sis issues of U. S. Camara. You can have each issue delivated to your home or studies flat and securally packaged, and you'll seve real money bestder if you order your copies in combination with U. S. Camara Annual 1940. Fill out the order form ballow!

U. S. CAMERA PUBLISHING CORP., 122 East 42nd St. New York C	Sity.

of fuse so that service is interrupted while new fuses are put in place A new fuse, recently developed by Littleliue Incorporated, is of unique construction, designed particularly to prevent such interruptions it has a simple fuse link, a resistor element which provides the heat inertia, or time lag, and a spring

On severe overloads, the fuse link melis as a convential fuse would do, on prolonged but not severe overloads, the resistor heats up and melis the fusible alloy. The spring serves not only to open the circuit completely after the fusible link has melted, but also takes up the expansion of that link due to repeated heating and cooling.

SHOULD EXPECTANT MOTHERS SMOKE?

S MOKING does not have any good effects on the mother during pregnancy However, climical experience would indicate that a moderate use of tobacco is not harmful to the mother or to the baby. When a woman smokes excessively, it is usually suggested that she decrease her smoking during pregnancy and particularly during the nirsing period.

Many physicians feel that the nicotine in tobacco may have a deleterious effect on the baby, but there is little scientific evidence to substantiate this view. Nicotine, however, does pass through into the mother's milk, so that excessive smoking may result in toxic amounts of nicotine being absorbed by the child.—Journal of the American Medical Association.

ILLUMINATED TRAFFIC MARKER SET INTO HIGHWAY

O F the numerous attempts that have been made to provide safety markers for lughtways for night driving, one that seems to provide more positive illumination than any other so far deresed is that definition of the control of the control of the control of illuminated founds. Inc., Inc., Ihis invention consists of a neon or other tubular light buried in the roadway under a transparent uncertail. Such lights would be built into roadways at important intersections, turns, or other danger spots, and it is believed that no amount of fog or glare from approaching arrs would prevent their boung seen hy a

When Mr Greene first conceived this idea he consulted with a number of people regarding a transparent material which would stand traffic wear Some people told him the scheme was impractical, but he finally found that a transparent plastic would withstand not only the weight but also the surface wearing effect of passing cars and trucks. In accompanying illustrations we

Above: One unit of the illuminated traffic marker. Below A plastic test block set in a busy highway

show a sample unt of the illuminated guide ine and also a picture of a test block of a plastic material made by Monanto Chemcal Company which was set in a busy street of Little Rock, Arkansas, for nunmonths. At the end of that time, during which an average of 9000 cars per day passed over it, the plastic substance showed on apparent depreciation of the surface and it ransparency was as good as when the

SCIENCE TO THE AID OF

N OT all inventions are made with a definite use in mind Only too often one may result from a great amount of research and then much more research is necessary to find what it is good for Polarioid, a material which polarizes light, falls in exactly that class. Originally, it was con-

sidered for an important use in the headlights of cars to which it has not as yet been adspted. It had, of course, a definite place from the beginning in scientific work, but practical everyday applications had to be found for it. Work to that end has found for it a place in many industries.

It may, therefore, not be so surprising to learn that this rapidly growing invention has been adapted for the beauty parlor Because of the ability of this material to dampen light reflections, as we have explained before in these columns, it has been found to be an excellent medium through which to view the skin and see those blemishes which are partly or wholly invisible under ordinary light. Dr. Martin Grabau recently demonstrated in the salon of Helena Rubenstein what is called the "Po-laroid Dermascope," which employs this material. With it, it is claimed that an ohserver can examine layers of skin under the epidermis almost as though the outer skin surface were not there. Then by moving a control lever, he can throw the outer surface into even greater prominence than under ordinary light for the examination of surface blemishes. The assumption is that once the beauty specialist knows of the existence of hitherto unseen blemishes she can adapt her procedure accordingly!

PRESERVING PAPER

A NEW and improved method of protect by Dr Joseph Broadman, will attengthen paper by means of a protective coating which renders the aliest impermeable to air, moisture, and the like, so that it can be handled and preserved indefinitely. The coating does not increase reading difficulty.

In this process, a page of a newspaper, for cample, has fixed to each face at hin sheet of transparent paper, preferably of that type known in the trade as "glassine". These sheets of light-permeable paper at laid on the newspaper with any untable atheave, preferably a past of cold water and wheat four. They are then allowed to dry at ordinary noom temperature. The sheets of transparent paper increase the attempth

"Polaroid Dermacope" and, top, skin under ordinary light (left) and polarised light

and tearing resistance of the newspaper, so that it can be handled without crumbling. But the transparent paper alone will not protect the page from the effects of air, moisture, and age, so the Broadman Process provides a coating on both faces and the edges of the transparent paper covered sheet, thus hermetically sealing the printed or written matter against deterioration.

The protective coating is a composition consisting of a mixture of 25 parts of Maula gum or Manila copal and 75 parts of chaptal alcohol. East India or Pontinane gums may be substituted in the same proportion. The coating is applied by means of a rigid pad or spreading tool or perforated roller with a cloth covering, causing the formation of a leth-termeable, smooth coating.

If has been estimated that about two or three seconds are required to add the "preserving" coating to a coated double page of standard newspaper size, at a cost of 12 cents pur sheet. The entire process, including transparent paper and adhesive naternal, less than doubles the weight and thickness of the page of newspaper.—Shatley Frank

GROUP STUDY OF X RAYS

THE Westinghouse multi-view stereofunctional X-ray pictures to be viewed by groups of two to eight persons at a time Pol.-r.red light also is applied to X ray work for the first time in X-ray history by the multi-view stereoscope. The old-fash-

Multi-view stereoscope, in which X rays appear in three dimensions

loads atteroption which used to adomthe pation in the average American bone to the pation in the sevange American bone copy work in medicine and industry. The creation of a picture effect which above depth depends upon the presentation of two images, taken from alightly different view-points. Each eye must inspect only that image intended for it. This is usually accomplished by means of micrors or prisms. The polarized atteroscope employs two images or transparencies made in the usual manner. The method of illumination and impaction of the images, however, is new.

images or transparencies made in the usual manner. The method of illumination and inspection of the images, however, is new, axising from an interesting property of light. Two films are placed in illuminator boxes, et a right angles to each other, and ditted with Polucuid access. One illuminator has its access arranged to produce vertical polarization: the other, horizontal polarization: the other, horizontal polarization: the other, horizontal polarization; the other, horizontal polarization; the other, horizontal polarization and the polarization and the polarization and the other horizontal polarization.

From tough steerto TENDER STEAK

by Westinghouse

- When a friend unexpectedly happens to drop in for dinner, it no more than right that he take potluck for granted. But when we carefully plan a dinner, long in advance, most of us pretty much stick to the rule of serving the best food we can get.
- That rule was rudely broken last April, when one hundred and forty-six people sat down to dinner at a Cleveland hotel. It was a notable group—civic and industrial leaders, food experts, home economists, chefs, editors—people invited for one particular purpose, to taste a new kind of steak.
- They were not served choice beef; those steaks were not expensive. Average in quality, average in price, average in every respect—but one! This beef was treated by a new process, called Tenderay, which has the peculiar ability of making ordinary beef as tender and juicy in just three days as the expensive cuts the very finest hotels serve after three or four or five weeks' aging.
- The guests were delighted. The steaks, they said, were excellent. But they were not half as pleased as Mrs. Cleveland housewife who learned that from that day on she could buy the same kind of beef at her own store. Heard that for the

- first time she could buy steak without guess and without gamble and know that it would be tender always.
- The Tenderay process depends on a lot of factors; humidity, temperature and what not. BUT—and here is where Westinghouse research plays such an important part—the process would be utterly impractical without the newly perfected *Sterilamp which kills bacteria with light and keeps the meat fresh and sweet.
- · He would be a rash prophet who'd care to predict the uses commerce and industry and medicine will find for the Sterilamp. In Suffern, N. Y., a bank installed it over the teller's windows to keep germs from passing with the money. A poultry man says it solves his turkey raising problems, Restaurants, hotels, bars and soda-fountains-in ever increasing numbers-depend on Sterilamps to keep glasses sterile; meat markets and groceries to keep food fresh, to reduce spoilage and refrigeration costs. One of the country's largest hospitals has installed Sterilamps to sterilize the air in the operating rooms. Another in the nursery to protect babies in their
- Certainly Westinghouse, when this development started, did not know its ultimate scope. And that, after all, is the way of research and its great justification. It is an exploration into the unknown, it follows new paths and uncharted byways—not with the assurance of success; merely with courage and experience and knowledge, and sound common sense as a guide.

ELECTROPLATING

PLASTICS

ELECTRO-DEPOSITION of various types of synthetic resinous materials on metals by a new process was described in a recent issue of Industrial and Engineering Chemistry. The process involves the solution of the resin in an organic solvent and the subsequent formation of a suspeneion in mineral oil

The work to be plated, which may be copper, tin, or brass, is placed in the suspension and direct current applied. Satisfactory results were obtained, using 300 volts for five minutes. After the plating has been applied, the plastic is cured or not, depending on the type Tests showed that the deposits are satisfactory from the stand point of electrical insulation. The process has been used experimentally for coating small trimmer condenser places.

RIINA

GERMANY is equipped to manu-facture about 25,000 tons of artificial rubber yearly, as comp with a peace-time need of 100,000 tone of rubber per year.

REFRIGERATION

AFFECTS FLAVOR

REFRIGERATION of many fruits and vegetables, as housewives have often complained, destroys the rich, delicate flavor for which those products may be noted. This is particularly true of tropical fruits such as bananas, pineapples, mangoes, and avocados. It is also true to some extent and avorages. It is also true to some extent for fruits grown in the temperate zones. Some varieties of pears, if held too long at 32 degrees, lose their ability to ripen and "go dead."

To prevent loss of flavor and texture, tropical fruits and pears should not be chilled until immediately before serving.

CIRCULAR SEAM WELDING

AN engineering advance has recently been made by the Chicago Metal Hose Corporation in the attachment of metal end-fittings and end-seals to metallic tubing by means of electric resistance welding. This means or execute resssance welding. This development, designed principally for use with stainless steel tubing and stainless steel bellows, permits the fabrication of completely sealed vacuum-right units free from soldered, brazed, or torch welded ioning of each brazed, or torch welded joints of any kind.

End fittings made from stainless steel have been customarily silver soldered to stainless bellows and tubing where corresive media or high temperature were to be encountered. However, to meet conditions

where exceptionally high temperatures and actively corrosive elements preclude even the use of silver solder, electric resistance welding has unique application.

Circumference seam welding, made possible through the development of specialized equipment, operates automatically and eliminates entirely the human element present in other welding or soldernel procedures. Extremely thin gages of metal can be handled with ease, and metals of unlike thicknesses or unlike analyses can readily be ioned.

TRANSPARENT PLASTIC HEEL

A NEW plastic heel is now available in sides list transparency, it has the novel feature of a removable hit. As the lift wears down, it may be taken off sud a new one snapped into place. The heel is a product of the General Electric Company's plastics division.

The accompanying picture is of a transparent model showing the construction. A

plastic of the polyvinyl methacrylate type is used for the heels. They are waterproof, noninflammable, and give a touch of sparkle to almost any costume.

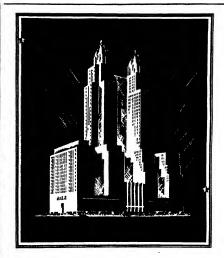

Some of the heels were "neonized" recently for stage use by the St Louis Minneipal Opera. They produced a striking effect on a darkened stage.

ACID HEALS PLANT WOUNDS

WOUNDS in plants are caused to heal by an acid which has been solated in crystalline form by research workers of the California Institute of Technology. For sale by SCIENTIFIC AMERICAN, 24 West 40th Street, New York, N. Y. 🔁 اليان بولون ables biologicals to retain their potency long after the time which, until now, had been thought to be their expiration date

The Lyophile process, as it is called, was developed at Mulford Biological Labora-tories and is essentially one of rapid freexing at a temperature far below the freezing point, together with rapid dehydration under high vacuum without melting or fusing the original frozen substance.

The containers are specially designed to maintain the desired vacuum and are so constructed that into the neck of each there may be inserted a tightly fitting rubber stopper. This is done after dehydration is completed and without breaking the vacuum When the stoppers are in place, the containers are flame sealed, labelled, and are ready for shipment.

The physician who uses the serum finds it a simple matter to restore it to liquid form. After filing and breaking off the neck of the container, a sterile syringe filled with distilled water is inserted through the rubber stopper. The vacuum draws in the water and the material readily dissolves. taking on the original properties which it possessed as a freshly made serum in the liquid state.

The new process brings to the physician, and ultimately to the patient, the original curative value possessed by a freshly pre-pared substance at the time of its highest notency.

AIR CONDITIONING

N 1933, there were only about 40 air-conditioned passenger cars on the American railroads, and most of them were diners. Today, the railroads and the Pullman Company operate 11,351 sir-conditioned passenger cars.

BIG OIL MOLECULES

FROM SMALL

SQUADRONS of German fighting and bombing planes now flying in Europe's skies are being lubricated by oils made by treating mineral, vegetable, and animal oils with an electrical discharge process which increases their viscosity. The "voltolized" oils, as they are known, are then blended with ordinary mineral oils to pro-duce what is said to be a superior airplane lubricant which has many of the valuable properties of castor oil.

The action of the electrical discharge appears to produce polymerization of the molecules of the oil (make large molecules out of small ones) and does it without changing the essential properties which make for good lubrication .- Science Service.

NEW TYPE BIG TREE

MOVER

BIG tree moving is now an established practice in landscaping properties and it is only natural that labor-saving equipit is only factivate that infor-saving equipment has been devised to keep costs lowered and generally to increase the speed and efficiency with which large specimen trees may be moved and transplanted.

Over a period of the last 10 years, an

eficient type of tree-moring equipment known as the Buts Tree Mover has been developed under extensive field tests. It is compact, requires less hand labor, is readily mobile, and bandles trees with speed and safety. Constructed of electrically welded seed and with all fast-moving parts equipped with ball or relier bearings, it should give years of dependable, troublefree service.

The equipment consists of a complete unit which can be installed on any truck baving a minimum of nine inches from rear spring shackles to back of cab. It is so designed that the cradle, in which rests the trunk of the tree to be moved, pivots in two directions, this factor, together with

Cradle end of the unit employed for transporting large live trees

chain suspension, insures proper support for any size or shape of tree. A second cradle, adjustable both in size and in its relation to the trunk cradle, is attached to the rear of the boom, supporting and protecting the ball of earth which may be up to 10 feet in diameter. The boom rolls on its hinges and is lowered to ground for loading. When transporting the tree, the boom is carried up and forward by a power winch driven by a 15,000-pound worin drive. An eyebolt, attached through an adjusting winch to top of boom by cables which pass on each side of the tree, is placed through the ball of earth and affixed to a horizontal plank underneath. The cables in turn are connected to a heavyduty canvas belt behind the tree trunk to simplify tipping and guiding of the tree.

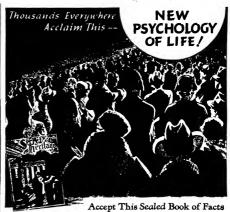

Carried in a horizontal position with the top forward, the tree resis on saddles at each end of the boom. This latter is operated by roller chain and worm driven sprockets, which control tipping of the boom downward and a leverage, powered by the same roller chains, controls upward tipping of the boom.

The Butts Tree Mover is also used in

The Butts Tree Mover is also used in pulling and loading stumps and is well adapted for use on many kinds of construction jobs.—C. F. Greeves-Carpenter.

NEW SYNTHETIC SOLID PRODUCES UNUSUAL TRACING PAPER

AN entirely new type of tracing paper A combining the transparency of oil treated sheets with the permanence of natural 100-percent zag papers is a recent newledgement of the Keuffel & Seer Company. The new paper is named Albannea. It is made of long-fiber, clean, white rags, and is treated with a new crystal-clear synthesis could make the company's taboratories. Bocause this new transparenting agent is free from oil

Have you unrealized hopes? Are the better things of life always just beyond your reach?

Times have changed—but have you? Do you still believe that some were born to have eventful lives—to have fame, fortune, and power, and still others destined to be mere plodders? Are you able to demonstrate a change in your affairs, to put your circumstances in order, and move forward to a better station in life? If not, it is time that you adopt a new psychology of life and learn to MASTER YOUR PROBLEMS.

It takes no greater mental effort to achieve results—when you know how. Successful living is the oldest art in the world. It consists of developing initiative, foresight, and the ability to combine experiences into new and workable ideas. The knowledge of this art was acquired in centuries past through the personal sacrifices of the ancient sages, teries. Their discoveries of the secret functionings of man's mind have been preserved by the Rosicrucians, an age-old, world-wide fraternity (not a religious organization).

The Rosicrucians Offer To You

—if you have the courage to break away from limited forms of thinking, these same simply expressed truths of life, which have led thousands to a joyous method of better living. If you are sincere—use the coupon below and secure the fascinating /ree book, "The Secret Heritage," which tells how you may receive this knowledge.

PROTECTING COPPER SURFACES

THE New York World's Fair, besides being an extraordinary speciacle, proved to be a testing ground to show the lasting qualities of paints, colors, and protecting contings. Of particular interest is the use of Glyptal, an alkyd resin, which has proved its ability to maintain the luster and characteristic color of copper sheets which it protects. On the exterior of the General Electric Building are thousands of square feet of thin copper sheets, protected with a coating of this material, which have retained their pristine appearance during many months of exposure. This first actual long-term test of Glyptal under such conditions indicates many other possibilities for its use in many industries.

ELECTRIC FURNACE USES BLANKET OF GAS

R ESEARCH metallurgists have intro-duced a new steel-hardening furnace that uses a "blanket" of gas to prevent "singeing" the metal while it is toughened at temperatures as high as 2000 degrees, Fahrenheit.

By means of a delicately balanced atmosphere of pure hydrogen and nitrogen, this automatic electric furnace is able to harden many steels gently without quenching them in oil or water, thus channeling distortion and formation of scale.

The furnace is approximately seven feet

RISTO IMPORT CO., INC.

Air-hardened steel scratches glass,

long and so designed that a piece of steel passes through it at varying stages of heat, ranging from approximately 1300 degrees to 1750 degrees, Fahrenheit, before it cools in an air-cooled tunnel. Maintenance of atmosphere of oxygen-free gases inside the furnace prevents any reaction in the steel which would distort or mar the metal. The steel shows no outward evidence of having passed through the fiery ordeal.

Pieces of ordinary steel, polished to a mirror finish, retain their finish after a fourhour hardening treatment in the new apparatus, report Westinghouse engineers The same steel would burn up if it were subjected to such high temperatures in an ordinary furnace, because of the oxygen in the atmosphere.

The combination of controlled atmosphere and temperature now enables the metallurgist to harden steel pieces in their finished form with a resultant bright finish and without the expense and delay of additional machining.

INCREASING THE BEARING CAPACITY OF PILES

RECENT investigations for the purpose of economizing pile foundations have developed an interesting method for increasing the bearing capacity of piles by covering them with a thin sheet of aluminum metal and sending an electric current through the soil. Preliminary small-scale tests performed revealed the formation of an entirely new and hardened soil structure in the vicinity of the electrodes. Tests also revealed that the hardening is not simply a drying of soil, but is irreversible since aluminum compounds are precipitated in the soil by the electrical process, cementing the mineral particles of the soil.

With small-scale tests, the bearing capacity after treatment increased up to between 10 and 30 times the original. By pulling the piles, the hardened section around the electrodes can easily be seen. Large-scale tests encouraged a practical application at a bridge foundation. A few timber piles about 60 feet long were covered up to about 25 feet with thin aluminum and driven under similar conditions in the near vicinity of common piles without aluminum. The distance apart of the aluminum piles was between six and seven feet, and electric curreni was sent through at between 90 and 220 volts. Though the subsoil conditions

AERIAL MAPPING FOR HIGHWAYS

THE fastest and cheapest way to secure an inventory of any area is to have it photographed from the air. With highway planning now covering whole states and requiring more and more inventory data, modern methods of mapping based on aerial photography have recently been developed to permit economic methods through the use of simple instruments and devices.

In making topographic maps by stereoscopic methods, the camera used for aerial photographs is of the precision type. Flying is done systematically so that the required overlays, both in the direction of flight and sideways, will be consistent. An aerial photograph does not show any depth, but with two photos partly overlapping and taken from different positions, it is possible to adjust them on the table at a certain distance from the eyes so that there are two images which merge into one having depth in addition to previous characteristies. To aid in viewing, a stereoscope is used.

Where the nature of a contemplated project involves the purchase of land, it is safe to say that the mapping of property hy this method on a scale of 1:12,000 is just as accurate as if the surveys were made by transit and tape plotted to this scale.-Eric Haquinus, in the Texas Engineer.

TRICHINAE IN AMERICAN SWINE

TRICHINAE, the muscle-boring para-sites that cause painful and occasionally fatal illness in enters of inadequately cooked pork, are widely distributed in the United States, reports Dr. Benjamin Schwartz of the U. S. Department of Agrieulture. In grain-fed swine, however, they are not nearly as abundant as in those fed on garbage. On the basis of thousands of examinations of slaughtered animals, Dr. Schwartz gave the percentage of trichinae-eontaining carcasses as less than 1 for graincommining cercases as less than 1 for grain-fied hogs, whereas it was 5.7 percent in garbage-fed hogs. The greatest bulk of hogs slaughtered in the United States, Dr. Schwartz added, are grain-fed.—Science Service.

SOLUTION TO THE PROBLEM OF THE WEIGHTS

AST month the problem offered was one concerning a set of eight weights for use with a beam balance. The weights were to be capable of weighing to the nearest ounce any object up to, and including, 205 pounds. Each could be used on the left scale pan, on the right, or not at all. It was required to find the magnitude of each weight, prove that eight is the least number, and that the eight weights have the least total weight of any set which will ful-

fill the conditions of the problem. Solving for the first part we reason that, ta weigh one ounce, it is necessary to have a 1 oz. weight In order to weigh two ounces we may select an additional I oz weight, a 2 oz. weight, or a 3 oz weight. We choose the 3 oz., because together with the 1 oz. weight it will enable us to weigh not only 2 oz., but 3 oz. and 4 oz as well Similarly, in order to weigh 5 ounces, we select a weight equel to two times the sum of the weights alreedy chosen, plus one For example, (2) (4) + 1 = 9 oz Reasoning thus, it follows that the right weights are 1, 3, 9, 27, 81, 243, 729, and 2187 ounces; a total of 3280 ounces, or 205 pounds Solving for the second part, we see that

since there are three places where the weights may be placed, there will be 3' different distributions of them From this number we subtract one to account for the case where all weights are on the shelf. The remeinder is divided by two because for each "out of balance" on the left side there is one on the right. This evaluates to $\frac{3^{2}-1}{2} = \frac{6561-1}{2} = 3280$

$$\frac{3^{4}-1}{2} = \frac{6561-1}{2} = 3280$$

It is apparent from the nature of the formula that a number smaller than eight for the exponent of three will give fewer than 3280 weighing combinations, which was a con-dition of the problem Eight is therefore the least number of weights.

For the third part of the problem, obviouely it requires a minimum of 205 pounds to weigh that much on a beam balance. Since the eight weights add up to only that amount, it follows that they have the least total weight of any set which will meet the conditions of the problem.

resented before a meeting of the American Chemical Society. Dr. Cadwell is director of tire development at the Detroit plant of United States Rubber Company

This somewhat astonishing conclusion is the result of a series of scientific tests and a research over the past three years in the company's laboratories, Dr. Cadwell re-The scientist was reserved in his report and comment, but other researchers pointed out that the discovery had possi-bilities of great importance to industry and

Dr. Cadwell told the Society his conclusion rested on the remarkable fact that rubber differs from most, if not all, other natural materials in that the "harder rubber is worked the greater its mechanical fatigue

"Indeed," he reported, "if rubber is used properly as a spring it can be made even to outlast a steel spring. If metals are to be worked in vibration, all engineers know that the longest life can be expected for a unit in which the metal is under minimum stress or load. For rubher, the opposite is true; the shortest life occurs when the rubber is worked under low loading or low stress conditions.

LOW-TEMPERATURE FIRING FOR NEW

CERAMIC MATERIAL

THE high cost and hazard of kiln firing. which often discourage ceramic and pottery work as a hobby, school craft, or small commercial venture, have been banished by the development of a new cley by Ettl Studios, Inc Ceramite, as this clay is called, requires no treatment other than baking in a kitchen oven for 20 minutes at 250 degrees, Fahrenheit, to produce a product having greater durability than ordinary clay fired at 1800 degrees.

Also available is a full line of color glazes which can be applied with a brush or spray, blended or applied over each other, and rendered permanent by oven haking for 45 minutes at 250 degrees, Fahrenheit.

PROBLEM: THE SWIMMING DOG

OR the past few months we have been FOR the past few months we have been offering our readers a variety of mathe matical problems. Judging from the letters received, many people have really enjoyed wrestling with them. There seems to be a sort of esoteric satisfaction in arriving at a solution after an hour or so of brain work Can you solve this one?

A man is standing on a river bank, on the opposite hank is his dog. The man whistles and the dog, being well trained and very ohedient, jumps into the river and starts swimming, always headed towards his master. The man is represented by "O" in our diagram, and the dog's starting point by

"P." The river is 0.48 miles wide and the dog started from a place 0.14 miles below point directly opposite the man. (In other words, the man and his dog were a half mile apart.) Now, if the river flows at a rate of one mile per hour and the dog swims at the rate of two miles per hour, how long will it take him to awim the river? Remember that at all times he is swimming towards point "O". The answer is 22.8 minutes and we will publish our solution next month.

As usual, any correspondence relative to this or any of our previous problems should be addressed to Lieutenant-Commander Leonard Kaplan, in care of Scientific American, 24 West 40 St., New York, N. Y., and it will be forwarded unopened.

YOUR FIREARMS

Conducted by A. D. RATHBONE, IV

INTEREST IN FIREARMS is traditional with American men; science has so developed them that millions yearly find sport and recreation in their use. Hence this monthly department presenting a while variety of divension regarding frearms, their handling, and their accessories. Suggestions from readers will be heartly welcomed.—The Editor.

TENITE STOCKS

WHETHER or not we've all been aware of it, this stuff called Tenire has been with us in many ways for some time. Both hands have clasped it as we've gropped the hands have clasped it as we've gropped the in the property of
something of a str in firearms circles. Product of Tennessee Eastiman Corporation, Tentie is made from Eastman collosies acetate, as thermoplastic and adaptable to both compression and injection molding, its attributes for gun stock are low thermal conductivity, low water absorption, compressive attempts of about 4000 pounds per square inch. In conducting fing tests, a Tentie stocked shotgen was clamped in a shooting pack, shoulder price resumg against a solid block so that the solid fring, the hard tubber butt-plate crumbled from constant hammering, while the plastic stock showed no fracture or distortion.

Shortly after the Stevens announcement, criticism was leveled at the alleged shrinking tendency of Tenite when exposed to a maintained temperature of 140 degrees, Fahrenheit. It was likewise charged that Tenite would soften and possibly warp in a continuous heat of 160 degrees, Fahrenheit, that acid or alcohol might blemish or soften the smooth, walnut burl-like finish. Although disapprobation was also expressed concerning stock measurements, we're momentarily more interested in the shility of Tenite to "take it" than in gun specifications. However, here's how Stevens lists them gun 14 available in 12, 16 and 20 gage with blue forged steel barrels, matted rib, fitted with two white bead Colasta sights, in 28 and 30 inches for 12 gage, 28 Inches in 16 and 20 gage. Right barrel is modified and left is full choke, chambered for 2%-inch shells. It is hammerless; has checkered, full-pistol grip, capped; fluted comb; paneled sides; 14 inch stock; drop at heel of 2%, at comb 15% inches; positive extraction; and weighs from 6½ pounds in 20 gage to 7½ pounds in 12 gage.

In 12 gage.

To determine effects of chemicals and reagents on Tenite, Tennessee Eastman Corporation conducted a series of tests in which dried, weighed, and measured

samples of the plastic were immersed for 84 hours in 85 directs acids, slabels, slist, alcohols, organic exters, solvents, essential solution, and macefulaneous chemicals of varying solution strengths. From this list we endeavored to select those regents to which a gun stock might normally be expected to be exposed in the gamist of carriess human actions, climinating such unlikely hazards as hydrochlora acid, solution hydroxide, and selection of the selection o

Stock, fore-end, and sight piece of a new shotgun are of Tenite

lemon, pennyroyal, and wintergreen, concerning which Eastman texts showed that henzene produces a "slight blustering," oil of wintergreen a "slightly rough surface," sodine a "brown timt," mercurochtome s "pink timt." Otherwise, "no change" was reported in the surface of Tente after exposure to these reagents which we selected from the entire 55.

Not doubting the Eastman laboratories, but solely in an effort to test Tenite with both reagents and vicissitudes to which an extremely careless gunner might uninten tionally expose his gunstock, we conducted a few "home-made" experiments. We procured samples of the plastic and smacked one piece with a hammer to simulate a hard fall or a blow of the stock against trees and rocks. The result was a much smaller dent than the same force would have made in a piece of walnut. We sacrificed a bit of 90-proof whisky in a 24-hour immersion test without effecting the slightest blemish. Lemon juice, gasoline, iodine, mercurochrome were all negative, save for the expected stains from the latter two reagents. We laid a lighted cigarette on a slab of Tenite and allowed it to burn to the end. The result was exactly what we've been chastleed for in the instances of the piano and the drop-leaf table.

As to the danger of a maintained temperature of 160 degrees, Fahrenheit, Frank T Green, Assistant Superintendent of the Stevens Company says, "... among our laboratory tests, we subjected a stock molded from this material (Tenito), to a set in a closed electrical over where tenperatures could be maintained consant for a long period of time, and we were able to subject these stocks to a temperature of from 100 to 200 degree, Fabrendeit, without any apparent distortion." We shudder to think that any person could conceivably do to his gunstock all that was done to Tenne and we rather think that, moder as its durable qualities are concerned, the results speak for themselves.

FOR GUN COLLECTORS

TTS a far cry, indeed, from a Tenite anocked shotgun of the 20th Century to the Austran made specimen of wheel-heel "sporting full" of 1655 when we recently imported at the exhibit of the International Studio Art Corporation, formerly a part of the William Randolph Hearst collection, and now being disposed of Speciations of this infe, expressed in the modern maner, are; blued, ordigonal barrel; fixed leaf rear sight for point blank shooting with adjustable folding leaf for elevation (fancy that—"elevation" in 16651); rifled with eight, deep, narrow growers; length, 44 inches, weight, 8 pounds, 541 ounces, caliber, A3

Not to know where or when one massumble aerose a really fine specimen of the early gunsmith's art, but to be able to evaluate such a find, and to couple with it all an active imagination, probably constitute the primary couponent parts of the fascinating hobby of anisteur antique gun collecting. Our own imagination certainly needed no urging when, in runninging needed no urging when, in runninging strong the part of ducling pustols which we found the pair of ducling pustols which spat lead at each ofter on Startidy immoring, April 28, 1826. For on that date, with those arms, at a secluded upon above Little those arms, at a secluded upon above Little

Dueling pistols that were used on the field of honor 113 years ago

Falls Bridge, Virginia, John Randolph and Henry Clay respectively sought and delended honor. No one was hurt, homor was vindicated, dueling went the way of the muzzle loader, and now, 13 years later, thus fine pair of pistols is booking for a new owner. Meanwhile, our imagenation ranbles on in the realm of ancient firearms and those who used them.

We've considerable interesting information on tap concerning the inauguration of amateur collections of old firearms and if you're interested in learning how to begin, where and what to look for, we'll be only too glad to pass it on.

EUROPEAN GUNS

AVAILABLE

NO one can prophesy what new twists the European war will have taken by the time this appears in print, but we have recently been informed by Abercrome be & Fitch, Franse Bannerman & Sons, and Stoeger Arms Corporation, three of our largest importers of foreign made sportsmen's arms, that the importation of those very excellent Belgam and English abottums and riles has not thus far been serously affected. Save for the German market, where the situation is, rather naturally, somewhat different, imports are expected to the international content of the content of the company of the content of t

Although all British gun manufacturers are reported to be busily engaged in wartime operations, and although their pers nel has been affected by calls to the colors, Messrs James Purdy & Sons, Boss & Company, E J Churchill, Ltd , W. W Greener, James Woodward & Sons, and others are continuing to make the fine quality guns for which they have so long been fam There has been no perceptible break in the import of Belgian firearms and save for a momentary hill at the outbreak of the war, British imports have to date proceeded normally. Despite the discription of German slupping, Abererombie & Fitch have just reported the receipt of a shipment, via

THOSE VACATION

PICTURES

THE vacation months are gone but the negatives remain, and with them your responsibility for carefully evaluating the merits of each and discarding those which, from every viewpoint, are of no worth. Among the discards will undoubtedly be sunrises and sunsets, mountain scenes with bald skies, certain landscapes, and so on. Even the best of us, carried away by a peculiar lighting or misled by a touch of color which might have been effective in color but not in black and white, take a number of shots during our vacations and at other times which bring disappointing results when fished out of the developer tank Such incidents are nuggets of expersence which are to be valued rather than deplored. The next time you will be more careful and hold your fire, or try some other angle.

Among your most interesting negatives will be those of people, particularly children. Some of them, because you may possibly have had to work fast and get your subject on the fly or were handcapped in some other way, may not be everything that might be desured as to composition. However, do not give up on this account; there is always the opportunity of taking a piece out of the negative and projecting it at a suitable angle. The "Rural Portraut" illustration did not present any great difficulty with this group of eight children of vanous ages. The slow owas conveniently handy;

the lighting would have been better if the faces were more in the shade, but the squints here and there lend an atmosphere of humor to the picture.

Valued above others will probably be those pettires which illustrate your vacation experiences. An entire series or group of prints may be assembled to illustrate the experiences of living as a farmhouse in the country. One such pieture is that of "Sunrise" taken at 6:30 o'clock on a September morning. In composing this pieture in the camera, it was thought best to concentrate on the outdoor scene and include only sug-

"Rural Portrait"

gestions of the cot on the left and the wooden bench on the right.

Inevitably, there will be sunset pictures Two examples that appear to have "come out" with fair success are "Sunset" and "Place's Pond." The former was shot on the way home from a short excursion. It seemed to deserve photographic attention because of the arrangement and shapes of the clouds and the interesting foreground which, of course, had to be shaded somewhat in printing to allow the greater printing exposure required for the clouds.
"Place's Pond" was one of a series of shots during a sunset. The quality of the water and the delicacy of the sky made a shot imperative.

"Barn Texture" is an example of the type

"Sunset"

of shot that may interest both the pictorial-ist and the antiquarian. This also might be part of a series showing different parts of the barn, exterior as well, possibly, as the interior. The lighting has to be watched carefully, of course, in order that texture may be revealed in the most eloquent way. In printing your vacation pictures, make a special effort to concentrate on a few negatives each acesion rather than attempt to work through the night and try, willy-nilly, to finish up the whole batch all at

"Place's Pond"

once. If you print only a few, you will know that your best work went into them because you will not be tired; if you print many, those towards the end of a weary evening are bound to suffer in quality. When you are through with the nega-

tives, return them immediately to their enclosures which should, of course, be provided when the negative strips are rem from the drying clips and cut up for filing It is so easy, when many negatives are being printed, to let them lie around after an eve ning's work, to gather dust and possibly suffer accidental nicks and scratches

Study your vacation negatives and see where this or that one may have been improved or why this one failed and that one is absolutely hopeless. You will learn much from such careful study that will help yo not only during vacation next time but all through the other seasons of the year.

CLEANING LENSES

PERIODIC cleaning of the camera lens A PERIODIC cleaning of the camera lens should be one of your regular hobby duties. Carefully remove the lens from the camera and brush all surfaces with a camel's hair brush to remove grit and dirt. Wipe the glass with a sponge moistened in spirit. Make sure the sponge is absolutely clean and free of dirt. Finally, polish the surfaces with chamois. Or breathe on the surface of the glass and polish gently with an old, soft, and well-washed cambric or liuen handkerchief.

LIGHTNING SPECIALIST

A FOUR-FOOT lighting rod erected on the tower of New York's Empire State Building provides Bill Eason, General Elec-Building provides Bill Eason, Ochean Elec-tric engineer, with unusual picture material of scientific value, according to a story in The New Yorker. Mr. Eason's exclusive job ane New Yorker. Mr. Eason's exclusive job during the thunder-shower season, May 15 to October 1, is to come down to New York, watch for lightning and take pictures of the bolts as they strike the Empire State. The pictures plus the data are relayed to the home office.

The equipment includes three high-speed cameras in a room on the 39th floor of the building at 500 Fifth Avenue, at Forty-

VOIGTLANDER RRIIIIANT

Unique Mirror Camera with F4.5 lens in Prontor Shutter

The Brilliant V6 is unique because no other camera has such a large bright and clear view in the finder. A glimpse at the finder and you know whether your subject yields the desired picture effect.

Sport scenes requiring especially fast "follow up" with the camera are greatly facilitated by the frame sport finder in bood.

The Brilliant takes 12 pictures 21/4 x 21/4 on standard 120 film. has an automatic stop to prevent over-winding and a built-in "hold-all" compartment to carry filters, etc.

15.00

Budget Payme may be arranged. Mail orders filled.

110 WEST SOND ST M.V

second Street; two oscillographs for recording the duration and intensity of lightning strokes, in the Empire State tower; and a fourth camera on the roof of a building at Eighth Avenue and Thirty-fourth Street, which gete the lightning "in profile." The latter camera is operated by remote control from the Fifth Avenue office.

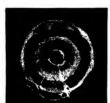

When one of his storm tipaters rings Mr. Eason to the phone, the routine is for Mrs. Eason to taxi from their apartment at 10 Park Avenue to get the cameras ready at 500 Fifth Avenue, while Mr. Eason hurries to the Empire Tower to start the oscillographs, after which he taxis to the Fifth towards after which he taxis to the Fifth total darkness and a time clock is punched to record the instant a picture is taken.

As he works, Mr. Eason talks into a microphone attached to his lapel, a record of his comments being engraved in wax, which Mrs. Eason transcribes the next day for the home office.

The Empire State has been struck by lightning 92 times in the last four years, but no one is ever hurt. Some of the strokes have exceeded 22,000 amperes and have lasted more than a second. It takes about six-tenths of an ampere to light an ordinary 60-watt electric-light bulb.

GLASS PICTURES WITHOUT NEGATIVES

IN a recent letter, E. L. Hettinger, of Reading, Pennsylvania, writee ue about his experiences in the making of prints by enlargement in his apecial field of technical glass etudies, and sends us a beautiful

Without a negative

example of one of the prints he has made. "The matter of making chalgements without negatives," Mr. Hettinger writes, "has been an old stunt employed many times him yofity-five years" of experience. There were times when we would take a piece of lace, or a piece of geometric chipped glass, and place it in the enlarger on a to make a border for some of our negatives. Naturally, this all occurred in the old days when things had to be fancy so as to be attractive. Later on, this experience helped me in my work on heat-treated glass. The man problem was to try to get some field about

the harmonic vibration point of glass.
"To break thousands of pieces of glass and make negatives, and then enlarge them was far from eatisfactory. Under these circumstances, I tried the old stunt of using the glass in the enlarger without making a negative. I found that little if anything

was lost in the print. In the illustration (reproduced here), a steel pellet hit the center of a prece of glass as shown by the inner errele. There was a vibratory motion, and then the energy dissipated from these concentric rings, and showed a fracture which again reverted back to the ring vibrations.

Without trying this experiment, you would hardly know how much was lost in making a negative and then enlarging it. For this reason, I have adopted this method of making enlargements without making negatives, because it saves a lot of time, and one does not lose any of the minute details that are required for studying the subject."

JUST A DETAIL

THERE is a story going the rounds con-cerning the folly of being didactic among one's peers. It seems that a member of a camera club requested a fellow member to develop a dozen negatives for him. Presumably wishing to make sure that no mistake would be made in the processing, he gave complete instructions including the wholly unnecessary one of closing the darkroom door before beginning operations. All these instructions, to the very letter, were set down in writing, and were followed without change. However, one very important step was omitted there was nothing to the effect that the white darkroom light should be turned off before operations were begun. The darkroom worker mischievously went right ahead with all the other instructions, including the removal of the film from ite covering in the ruinous light. Of course, the films were hopeless from the start, but he

develop these for me?"

A SPECIAL effect, full of warmth and glow, is obtained in portrait lighting by having the subject partly illuminated from below, as in the illustration, "Mary Ellen." This type of lighting is usually called "dramatic" but when so employed it

developed, fixed and dried them, carefully

wrapped them up with interleaving between the negatives and handed the finished work,

very solemnly and innocently, to the owner. The latter stood aghast at the 12 black nega-

tives but took the incident ln good grace when his written instructions, with the fatal

omission, was shown to him. Luckily, the pictures could be taken over again without

trouble, and were. The next day the didactic member again asked the same favor, but this time he simply said: "Will you please

"Mary Ellen"

ardinarily constitutes the main and only light used. However, a softer effect is obtained by having the light come from above, back of the subject and reflected from below by a reflecting screen so placed as to give the effect sought. This was the procedure in the present linguispace.

AWARD FOR

CAMERA HEADLINER

NOR the best foreign newarcel of the year, A. T. Hull, Jr., of Pathe, says an announcement from the makers of the Lcica, was awarded the plaque of the National Headliners Club at a dinner held recently in Atlantic City. The film for which he was given the saward aboved the terrible holocause of the bombing of Canton. Like many of the cameramen covering the hostilities in China, Hull was never without his Leica, and he continually used it for making atilla, many of which have appeared in Life and other national publications.

SPOTTING KINKS

D LACK lines and black spots on prints, caused by transparent lines and holes in the negative, are usually more difficult to remove than spotting out light defects. One effective way to remove both lines and spots

You Can Win one of

PRIZES

EVERYONE who owns a camere
has a chance of winning a valuable prize Plen new to enter your
prints in this contest You may enter
any or all of the three divisions, but not more than two prints may be entered by one contestant in any one of the divisions.

Specific rules for this contest ere pub-lished below. Be sure to read them before you submit prints.

RULES of the Contest

- e i The groups will be judged independ-ently on the bests of pictorial appeal and technical excellence. The decision of the judges will be final. In case of a tie for any prize, duplicate prizes will be awarded to the tying contentants.
- e s. Prints must not be smaller than 6 by 7 or lerger than 11 by 14 Prints need not be mounted, but may be at the contestant's option
- 3. Photographs must be packed properly to protect them during transportation
- 4. Non-winning entries will be returned only if sufficient postage is included when the prints are submitted
- a E. Each entry must have the following date written on the back of the print or mount Name and address of contestant, type of easeers, and film, enlarger and paper used.
- e S. Contestants may submit no more than two prints in each group but may enter eny or all groups
- ? Prints must be in black and white. Color photographs are not eligible
- 8. Prize-winning photographs will become the property of Scientific American, to be used in any manner at the discretion of the publisher
- B Scientific American reserves the right to purchase, at regular rates, any non-winning entry
- e 10. No entries will be considered from professional photographers
- e 11 All entries in this cor test must be in the hands of the judges by December 1, 1839 Results will be announced in our issue deted February 1940
- 12 This contest i. open to all ame photographers who are not in the employ of Scientific American

This Contest Closes Dec. 1, 1939-All Entries Must Then Be in Hands of Judges

Address All Entries to

is through the use of ink eradicator. This should be applied a little at a time, remo ing the line bit by bit. The black defect cannot be taken out all at once. For removing small black spots, another method is to use a small spotting brush molded to a fine point and tipped with white spotting color.

The effect should be judged only after the color has been allowed to penetrate the paper at the treated point. If the result is color light, and a little gram the the too light, add a little gray after the first application has dried.

RATHING REACH

THIS suggestion is probably a little late for this year, unless you are on your way south, but it will keep until next time. "Stormy Weather Ahead," a low angle shot suggested by the darkening clouds, is a

"Stormy Weather Ahead"

subject that depends for its effect on the clouds, the nature of the lighting, and an exposure favoring the clouds. In this instance, the clouds covered the sun and an stance, the clouds covered the sun and am acrea which was inadequate for the foreground figure, suitably rendered here in practically a silhouette. The shot was made as the subject swung slightly backward from the hips and looked up toward the approaching clouds.

LAST CALL .

THERE is still time to enter the Fourth Annual Scientific American Photog-raphy Contest—but hurry, hurry, hurry: Entries must be in the hands of the judges by December 1. Doll up your best prints so that they look their finest, for one of

so that mey look their meet, for one of them may bring you a valuable prime. Full details of the contest appear on this page. Be sure to read the rules care-fully so that your prints will be eligible.

NARROW FORMATS

A PRINT does not necessarily have to A fall within the category of the regulation 5 by 7, 8 by 10 or any of the standard paper sizes. If the particular picture you have in hand looks better in a fersist which is narrower with relation to its length shari

"Make Money With Your Camera" Photo-Markets

This 144-page book tells what to "shoot," how and where. Gives directions for submitting photographs to magazines. Lists hundreds of markets for photographs, together with the types most suitable for each.

the usual ratio, by all means go sheed and print it that way. In the subject illustrating this piece there seemed nothing to do but treat it as you see it reproduced. The grand display of clouds is the principal attraction and their majesty is greatly emphasized by comparison of the towering masses with

"Majesty"

the small boats on the water below. The negative image had to be considerably "trimmed," but the effect and composition were greatly improved as a result.

IDENTIFYING PAPER EMULSION SIDE

CME vockers find difficulty while in the J darkwom in telling the paper resultance side from the unceated side. This is particularly difficult with smooth paper. There are three general ways of telling the coated from the unceated side. First, there is the familiar one of bitting a corner of the paper. The side that siticks to the teeth is the emulsion side. The other tellitale signs are that the emulion side looks more shury than the other and side that it has a tendency to curve inward, concave fashion.

WHAT'S NEW

In Photographic Equipment

If you are interested in any of the items described below, and cannot find them in our advertieing columns or at your photographic dealer, we shall be sad to tell you where you can get item. Please accompany your request by a stamped envelope.

Participon Easts. (\$12.75): Constant-context type enlarging state. Marks consist of four attys of thewysage formed steel, 1½ inches wide, helding paper firmly and naking for clean border line. Each pair of masks operated by single control button. Moving control button simultaneously moves both border strips towards or away from each other. Baseboard of asset provided with set grooves for 4 by 5, 5 by 7, 8 by 10, and 11 by 14-finch papers. Guides always ready for use without adjustment,

but are flush with top of base so that smaller put are mush with top of nase so that splanter guides do not affect use of larger paper sizes. Surface of baseboard finished in special silver lacquer which provides a focusing surface not easily affected by dust and grime. Frame of heavy metal, designed to provide adequate strength and rigidity in order to insure perfectly square borders and firm paper grip.

ARGUS JIG-A-MAT (\$6.75) · Resembles ordinary 8 by 10 enlarging easel; top covered by 13 separate and differently shaped mats made of red Bakelite which can be arranged to form almost unlimited montage combinations. Each mat has its number and indicator, so there can be no mistake as to paper areas exposed and those that are still to be exposed.

AGEA TEXTURE SCREENS (\$2.50 each; set of four screens with Agfa Border Mask, \$10). Available in four types three fabric textures identified by names Satin, Oxford, and Homespan, fourth, irregular pattern named Ripple. Screens measure 8 by 10 inches; can be used for both contact and projection printing, being placed in linmediate contact with photographic paper during exposure. Special precautions in manufacture are claimed to permit use of same contrast grade of photographic paper that is employed when prints are inade without texture screen. Agfa Border Mask (\$3) is 11 by 14-inch negative designed for use with Texture Screens. Mask provides 71/2 by 91/2 inch field with eiching-edge border

ROLL-FILM DEVLLOPING (\$2.95): Contains essentials for fine grain developing, including new F-R "Spe-cial" adjustable developing tank (adjust able to roll films of all popular sizes); fine grain developer, X-33; concentrated fixing hardening solution, Fixel; two spring film clips for hanging film to dry; complete in struction book containing darkroom infor

KODAK MONITORS SIX-16 AND SIX-20 (\$30 00 to \$48.50) : Features: automatic film-wind control and body shutter release which retracts automatically when camera is closed, aluminum alloy bodies and backs, new system of bed braces which provide 10-point support to maintain less and shutter rigidly in accurate position, mechanism to prevent double exposures. eye-level and waist-level finders; monitor turret with automatic exposure counter, field depth scale, range finder clip, and single push button to control both opening and closing; two tripod sockets as well as folding supports for leveling camera on table.

MASTERCRAFT; GRANT, SR.; ARNOLD EN-LARGERS: Three additions to Sun Ray enlarger line ranging from \$16.50 to \$75. enlarger line ranging from \$15.50 to \$75. Masterraft: takes negatives from Robot size to 2½ by 3% inches; geared trolley focusing unit. Enlarger only, \$22.50; with 3½-inch 1/4.5 Wollemash 33.750; with 3½-inch 1/4.5 Wollemash 1/4.5 Lenz; two condemans areaction focusing on focus and Projector: Wollensak 3-inch /4-3. tens.; two condensars, preciation focusing on geared trolley unit; revolving head for horizontal or vertical negatives; geared post, built-in red light filter, for us on A.G. or D.C. Enlarger only, \$42.50; with 3-inch /4.5 Wollensak lens, \$52.50. Arnold

BOOKS BOOKS • r

Amateur Photographers

New Ways in Photography, by Jacob Deschin. Eminently practical from every point of view, this new book contains nothing of theory and nothing that the advanced amateur photographer will not find valuable in one way or another. It covers the whole range of amateur photography, discussing such things as trick photography, photomurals, retouching, infra-red, and a number of other sub-divisions that will not he found elsewhere in as clear and concise a man-

So You Want to Take Better Pictures, by A. P. Peck. A friendly, factor-face chat with the camero owner who has his developing and printing done at the photo shops, yet wants to know enough about his camera and it was to enable hum intelligently to utilize it to best advantage. Over 200 pages, dozens of illustrations, \$2.10.

UNIVERSAL PHOTO ALMANAC AND MAR-KET GUDE. How, when and what to with your cameru; where to sell dif-ferent types of prints, \$1.00.

AMATEUR FILM MAKING, by George H. Sewell, A.R.P.S. Useful to the begin-ner as well as the expert movie maker. Tells about films, cameras, exposure, film editing, story telling with the camera, and so on, Illustrated, \$1.60.

CHAMPLIN ON FINE GRAIN, by Harry Champlin, A complete hand-hook on the entire subject of fine grain, in-cluding formules and how to com-pound and use them. \$1.85.

PHOTOGRAPHIC HINTS AND GADGETS, PHOTOGRAPHIC HINTS AND GADGETS, by Fraprie and Jordan. How to make all kinds of photographic accessories; from film clips to cameras to lighting equipment, and so on: 250 articles and nearly 500 illustrations. \$3.60.

PORTRAIT PHOTOGRAPHY, by H. Wil-liams. Fundamental principles of composition and lighting, paving the way to satisfactory results in this particular branch of photography. 84.35.

PHOTOGRAPHIC ENLARGING, by Frank-lin I. Jordan, F. R. P. S. One of the most interesting and authentic books most interesting and authentic books on enlarging. Its 224 pages cover every phase of the subject and 75 illustrations, many of them salon-vinners, show the value of correct technique, \$3.60.

JACOB DESCHIN, conductor of our "Camera Angles" department, will answer in these columns questions of general interest to amateur photoganswer in since cottains questions of general interest to amateur photog-raphers. If an answer is desired by mai, enclose a stamped, addressed envelope. Queries should be specific, but Mr. Deschin cannot undertake to draw comparisons between monufactured products nor to advise on the purchase of equipment or materials.—The Editor.

O. I have had some trouble with light leaking through the bellows of the camera. What is the proper method of testing for light leaks?-W. J. N.

A. One way is to remove the back of the camera, pall a light-proof cloth over the head and the camera and insert into the bellows a small 4-volt lamp in a holder connected to a pocket lamp battery. Examine the bellows folds, joints and corners. If and when the source of the light loak is discovered, repairs may be made by filling the holes with rubber solution thickened with lamp black powder, or the break or breaks may be covered with small pieces of black court plaster.

Q. How can I obtain the letters A. R. P. S. after my name?—B. W.

A. These letters stand for Associate of the Royal Photographic Society (of Great Britain) and are accorded to members of the Society who have achieved distinction in some field of photography. Membership is open to all photographic workers in all parts of the world. The first step towards the acquisition of the coveted letters is to fill out a regulation form and send it to the Secretary of the Society in London, accompanied with evidences of one's work. Periodically each year these applications are voted upon and if you are turned down once, you can apply again at a later time, with better evidences of your work.

Q. Where and how is distilled water obtainable?—M. J. R.

Distilled water may be purchased at the five-and-ten-cent store or at the drug store. Water free of the foreign matter con tained in water obtained from taps may be had by catching rain water in a non-metallic container, such as an enameled pail or crock.

O. I wish to take stereoscopic color transparencies with a 35mm camera. I am acquainted with the Leica equipa sm acquainted with the Loice equip-ment for this purpose, but can you tell me of any other equipment for taking and viewing these pictures?— D. E. D.

A. You probably are aware that stereo pictures can be taken with any camera imply by using a still subject and shifting he position of the camera between the two res a distance of about 2½ inches, two eyes of a human being As for viewing the resulting stereos, any regular stereo viewer accommodating this size transparency will be austable. An article on stereo photography appeared in our Camera Angles department in the November 1938

Q. I have had very little experience Q. I have had very little experience in photography and eannot spend much, but I will soon need an appar-atus for use in plant-breeding work. Can you advise what type I must get for clear anapshots of plants and also photomicrographs of plant cells and the like?—A. L.

A. The least expensive outfits for your A. The least expensive outnits for your purposes are the Argus and the Mercury, for both of which cameras special apparatus is available in these fields. The service departments of both these organizations will be glad to send you helpful data and auggestions

O. What do you think of taking two exposures on a single film without covering half of the lens? Will the pictures be sharp and worth enlarg--L. D. ing?-

A. This is altogether possible and is, in fact, an arrangement in regular use on viewtype cameras. A ground glass focusing-type camera is required and the proper negative masks must be provided so that one half of the film is covered while the other half is being exposed, and vice versa. If the focusing is accurately done there is no reason why both pictures on the same film should not be as sharp as one picture made on the

Q. Can you tell me where I can get

a list of picture agencies? - J. C.

A. Editor & Publisher, the newspapermen's organ, has a complete list of syndi-cates that buy photographa. The list was reprinted some time ago in an isaue of Camera Magazine, Philadelphia, Pennsylvenia.

Q. Is it possible and practical to make sensitized paper for use in making photostatic copies of printed -L. E. W.

A. Most hand sensitized papers do not have sufficient contrast for photostatic work. Rather, we would suggest the use of some such paper as Novaflex or Outline Special.

FINDING NEW SUBJECTS FOR YOUR CAMERA

By Jacob Deschin

CAMERAS too often repose in closest and bureau drawers because their owners have exhausted their own Innited resources of photographic subjects and have tured of repetition. With new vistas opened to them through the ideas suggested by Mr. Deschin, they will find new joys, keen delightin, imphotographic supinistance of the contract
is to say that this is one book which the ambitious amateur photographer cannot do without. (240 pages, 6 by 8½ inches, 24 excellent photographic illustrations, most of them full-page size.)—\$2.60 postpaid.—A. P. P.

SKEET AND HOW TO SHOOT IT

TO the skeet devotee this book will be a friendly, helpful critic in pointing out possible existing faults of form, stance, fit of gun, target lead, and other factors which may have tended to interfere with perfect scores. To the interprinced skeet shooter it will be a complete and competent gunde for the above named integers of the structure suggestions and extensive information on eyes and shooting plasses, clothing, field layout, and the entire game from the structure of the

THE STUFF WE'RE MADE OF By W. O Kermack and P. Eggleton

DIOCHEMISTRY is the central subject of this book, written by a staff member of the research laboratory of the Royal College of Physicians and a levelurer in biochemistry at the University, both of Edinorph. It contains a very great amount of dependable data, some of it quite technical but all of it lincidly explaned in elementary language and without pertense, centening around the efforts of science to understand the nature of life and its investment processes. No better book by which the currons outsider reader could gain at least a rough peared in many verse. (342 gages, 5 by 74 inches, 63 illustrations) — \$3.30 post-puid.—# 6.11.

SCIENCE AND MECHANISATION IN LAND WARFARE By Donald Portway

APPROPRIATE now in the study of details of the war in Europe is the new volume which, in addition to fundamental scientific principles, covers chemical axifacts, mechanization, railways in war, weather problems and stratosphere flight he work of the Royal Engineers, the work of the Royal Engineers, the work of the Royal Corps of Signals, artillery surrey, and war personnel. (135 pages, 5½ by 8% inches.)—\$2.50 postpaid.—F. D. M.

We can supply our readers with any of the books reviewed in this department. Prices quoted include domestic postage. Foreign prices are necessarily higher due to increased shipping charges.

A Monthly Department for the Amateur Telescope Maker

Conducted by ALBERT G. INGALLS

AT long last, someone has actually built and the spectroscope and spectrohelograph (not to be confused with the spectrohelocope) described in "ATM," thard and fourth editions. For some reason thus instrument never has been popular with the crowd. Arnold S. Mountfort, a portrast artist, 2200 Mountain Oak Drve, Hollywood, Calir, is the first maker (Figure 1). "The actual time, mostly in London," Mountont writes. "The recommended water clock driving mechanism (CATM, page 211).

mechanism ('ATM,' page 211) was not a success, as it always went in jerks due to the dark-slide's friction. Regarding the cost, about which you inquire, I cannot now state but, with a fair genius for getting material for nothing, the whole, including the coelostat, should not cost more than \$10 or \$12.

"The most difficult part was cutting and mounting the slits. By fixing the curved one on the end of a long piece of wood pivoted at the other end, I got a good and true edge by rubbing it against a piece of fine Carborundum stone for the male half and reversing them for the female." It was all intensely interesting

"It was all intensely interesting and well worth the trouble. My first photographs were terrible tragedies. The solar spectrum, though clear, was so over-exposed that it came out positive. But if there was nothing to work for it would not be half the fun. I have found no need for the long focusing rods or for a shed, a galvanized cover giving sufficient protection."

Mountfort, at the time he wrote the above, was painting a portrait of R. W. Porter to be contributed to a gallery of astronomers and telescope dosagners of our time, "in order that those who will be working the 200-nch in 1000 years," as Mountfort puts it, "may know something of the pioneers of this development of

IRST big hurdle to jump when undertaking a Schmidt astronomical camera has been the deep curve, otherwise a lot more Schmidts would be made by amateurs. The Lowers used 25 pounds of Carbo and played wet nurse to their granding machine for 96 hours, in 1932, when roughing a deep compared to the control of the control o

Fred Ferson, Biloxi, Mississippi, therefore suggested some months ago that an attempt he made to wangle the Corning Glass Works, Corning, N. Y., makers of Pyrex baby hottles and 200-inch mirrors, unto casting a batch of Schmidt blanks with approximate curve. Approximate Corner, and the control of the competitive
Figure 1: Mountfort and spectroheliograph

Advised, Corning stated that the most economical way for them to make these would be to rough grind the cavity rather than cast it in, as the molds are expensive; also, for some technical reason, to make the radius 36 inches. They found they could supply these at a little more than double the price of ordinary Pyrex disks of the same size.

Before announcing this fact it was thought best, however, to put these disks to actual test, so Corning sent Ferson a dark, 12% inches, 65-inch relatue, and he spit on his hands and went to but with it. Final report: He spent 12 hours and used two pounds of Carbo in despening the curve from 36 inches to 32 inches and truing it. Used convex tool of full diameter, which example the savey as fast as he plass: hence, no concerve mate vars useded. Metal tool also gave shallower pits, smoother surface, he states. In sum, he reported, it is now possible to grind and pollah a primary for an 1/2 Schmidt, bit an 1/3 Wright, by hand, is about the tidale required for a mixture of like

aize but common focal length. For this, we may thank Ferson and Corning.

AST month in this department it was hinted that James G. Baker, of the Harvard College Observatory, had designed a family of flat-field cameras (Figure 2) equivalent in performance to the Schmidt. The following is his description of them:

"Many years ago Schwarzschild set out to find the most useful system of two mirrors possible. He found that, although there

exists a system that is aplanate and anastgamatic on a flat field, it is of no practical use because of the total allhousting of one mirror by another. As a consequence, Schwarzschild renitroduced astigmatism and solved for the parametric equations of a family of aplanats with flat field. The best known member of the family is a system of two concess mirrors, at the concess of the control of the primary. Astigmatism in the system limits the available field of this reflector.

Improvements in the image quality of reflectors were of a minor nature until Schmidt introduced the idea that small deformations in an otherwise weak lens could be most effective in helping to eliminate the image defects of come and spherical aberration. Wright has generalized the original Schmidt camera into an entire family of Schmidt cameras and has shown that astigmatism cannot be eliminated on a flat field by correcting plate and one mirror alone. Wright's work in turn can be generalized to show that astigmatism cannot be eliminated on a flat field, even

when several correcting plates are employed, all separated, so long as the total powers of these correcting plates are of the second order with respect to the

mirror. Three mirrors with aspherical surfaces can be designed to give excellent performable make a surface and the designed to give excellent performable mathematically, but the allibuouting in such a system is hopoless. Thus, only more more possibility remains, and that is a system of one correcting plate and two mirrors. This combination preduces a two-parameter family of telescopes with a surface of the control of the designed of the designed of the designed of the designed of the overecting plate from the primary mirror and the distance of the potential plate of the designed of the property of the control of the designed of the property of the designed of the potential plate of the potential plate of the property of the designed of the potential plate placed immediately before the secondary, the tube length becomes extremely short compared with the focal lengths. For example, one combination produces a tube one sixth the length of the state of the state of the designed performance. For each short tube length all three of the curved optical surfaces are suphesion. The results of the state of the designed and the designed an

spherical mirror surfaces fortunately pos-

aspherical mirror surtaces iortunatesy pos-sess no inflection points.
"If the tube length be of no serious con-sideration, the two-parameter family in-cludes a remarkable one-parameter family, with tube length about % that of the Schmidt of the same focal length, such that the two mirror surfaces depart inappreciably from spherical surfaces. The curve of the correcting plate becomes much more shallow, and is not much deeper than for the Schmidt of same focal length and aper-

The reasons for the existence of the two

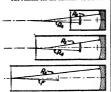

Figure 2: The Schmidt system compared with the two-mirror systems

parameter family can be seen from consideration of the Schmidt and Schwarzschild systems. Then, too, one can deduce the family from the Schmidt system One starts by considering the usual Schmidt camera with an additional plane mirror secondary, untilted, so that the curved focal surface is inverted and near the primary. By keepsurfaces coincident, and by variation of all the curves and separations, the curvature of field can be continuously reduced to the flat field here considered.

"Figure 2 shows an f/3 camera of short ength with an 8 degree unvignetted field, also the corresponding camera of longer tube length and spherical mirror surfaces. Moreover, for comparison purposes a Schmidt camera of exactly the same light gathering power, focal length, and un-vignetted field is shown. The apertures of the two-mirror systems have been adjusted to compensate for the additional ailhouetting and extra surface, absent in the Schmidt.

The advantages that can be pointed out for the two-mirror system are the extremely short tube length possible, with consequent saving in space and material, conveniin loading the plate holder, and the existence of a large, flat, unvignetted field. To give an idea of the importance of the field, if the customary large paraboloidal reflector were converted into this type in the same were converted into this type in the same tube, the number of square degrees photo-graphed per night would equal the number of square degrees photographed by the para-boloidal form per month, the definition at the edge of the useful field being the same, from a very conservative calculation. Fortunately, the two mirrors and plate-holder are close together in what is usually the stiffest part of the tube." In Figure 2 the spherical surfaces, tangent

to the true surfaces of the mirrors in the shortest type, are shown dashed. The mirror curves are exaggerated to twice their true dopths, the correcting plate surface many times, and the feest surface of the Schmidt

THE BLGINNER'S CORNER

THE experienced telescope user is often THE experienced telescope user is often less inclined to belittle the alt-azimuth type of mounting than is the beginner. With the equatorial type, because one axis is cocked over parallel to that of the Earth, it is necessary to keep moving the telescope tube in only one direction as the Earth axis perpendicular to the Earth's surfacethat is, at some angle to the Earth's axisit is constantly necessary to move the tube in two: for example, over a bit (azimuth) and up a bit (altitude). In practice this isn't nearly so much of a bother as it sounds; while the mounting is simpler to build. The clean, trim alt-azimuth shown was built by J. L. Wagoner of Pitt-burgh, Pa. It has a 6" mirror and a 7" aluminum tube The pillar is a piece of 4" brass tubing and the base and yoke castings are of aluminum

TELESCOPTICS

(Continued from preceding page)

IN the Journal of Scientific Instruments (London), August 1939, H. W. Cox, 47 Upper Green, Mitcham, Surrey, England, an amateur whose first Schmidts were described in the February number, describes in a six-page article his technic of making Schmidts. He sent us an extra copy of the article, which will be lent to those seriously doing Schmidt work who wish to ask for it, provided they will promise to return it promptly so that it may be passed on to others Cox will also send copies to genuine Schmidt workers, if asked. The paper would mean little or nothing to others, as the methods are in no way applieable to work on ordinary telescopes; Schmidts being advanced work.

ONCE a year a "nova" breaks out among telescope makers; verses Most recent poet is the proprietor of the Apex Monu-ment Works (gravestones!), 6815 West 27th Ave., Edgewater (Denver suburb), Colo., who offers the following outburst (novae are due to an overproduction of energy):

The Amsteur Mirror Maker By Anton Bohm

He walks at night, around a keg. on top a disk of glass He pushes forth and pulls it back—another piece For months and months he's kept it up, his patience etill intact One hundred miles he's surely walked around that circular track

He counts the minutes and the strokes, elliptical and streight
He fights against a turned down edge and spheroids
much oblate much oblate aboloid, hyperboloid, ATMA, TB.— words and terms that he can use with ultra-

And puts it on a testing stand to see what he oan see,
And squints along a resur blade and then he abouts
with size:

"At last! I see what seems to be a doughnut fat and round!" But though the shape is these shright, the depth is too profound.

The distance from the inner sone, compered with from the rim, Is much too far eway as yet Se ii appears to him

Again the weary grind begins It surely is no cinch. The surface must be right within one millionth of an inch a ninch is small, and you will promptly a how when he is done with his gigantic table?"

His planois lamp and ranor bisde—they will reveal to him The mirror in its perfect shape, correct from rim to rim

But that is not the only grief-experience he must gain in the not ine only green—experience as unus-gain.

It's finding scratches, siceks and pits that causes him much pain

Dust is a thing that he abhors—he flies into a tantum tantrum

When finding on his polished disk a grain of
Carborupdum

"Oh Wifey! Did you sweep the floor?" he hollers from his shop "If you insist on cleaning up, I'll surely buy a lock." "Indeed you'll not," replies his spouse, "I never yet have seen A place so gory, it's a fright—I'll never get it clean "Rouge over every thing I see It surely is a mess Rouge on my towels, yes on the walls 12's even on my dress"

But all hard tasks some to an end Some night the Poucaut test
WIII throw upon his speculum the shadow he loves beet.

The shape is there—the depth is right, at last the thing is done. He heaves a sigh of deep relief—some people call it fun It fun
And so will you, I dare predict Some day you'll
see (t—but
You nover will, till you've become a Telescoptic Nut.

PORKS, if made by casting from carefully ahaped patterns, may be made very pleasing to the eye but, if not, they somepressing to the eye but, it not, they some times fail to satisfy the telescope maker's feeling for beauty. A kind of fork that can be made with a lathe alone, yet which is pleasing to the eye, is shown in Figure 3. Otto C. Rasmussen, 57 Brunswick Avo., Troy, N. Y., designed this fork, in which he used 1½" steel shafting, a circular plate of ¼" steel and underneath it, two The telescope, a 6" of 50" f. 1 rollers. avoiers. The rerescope, a or of any L. 'a.'
is equipped with a motor drive mention
in triangular baseplate. The latter is
of angle iron with a '4s' steel deck. On

Figure 3: Rasmussen's neat fork

this deck are two double glasses and at the apices three leveling screws with locknuts. The hour circle is of the floating type. The square tube is made of 1/2" x 1/2" x 1/3" angle iron with diagonals of 1/3" x 1/3" strip steel

Rasniussen also made a nocturnal or horometer (Figure 4) for giving sidereal time. The handle is held perpendicularly, Polaris is sighted through the central hole and the straightedge is turned to line up on Beta Ursa Minoris. The pointer then shows sidereal time within about 5 minutes

BOTH "ATM" and "ATMA" recently underwent minor operations when exhaustion of stocks led to reprintings (notehaustion of stocks led to reprintings (note-not new chitunes). Misprints were cor-rected and in "ATM" a few changes made. Old note on p 333 discouraged refractor work, new one encourages it— things have progressed Note on p. 458 was replaced by one telling why photographic lens making is highly advanced work, because numerous novices seem to get the idea that making a photographic lens would be a "simple introduction" to telescoptics! Hallucination.

TRADE MARKS AND UNFAIR

COMPETITION
By ORSON D. MUNN

A TRADE MARK is an intangible asset of a business, yet its actual value may grow so large that it becomes the very foundation on which depends the whole structure of the business. Because of this fact, every business man should have available such information on trade marks as will enable him to judge with a fair degree of accuracy the desirability of any mark which he may be considering.

Here, in one handy volume, written in non-legal terms, is a simple yet comprehensive interpretation of the Federal statutes and the body of common law relating to trade marks and unfair competition.

BBILLS

(The Editor will appreciate it if you will mention Scientific American when writing for any of the publications listed below.)

Excitizative: A Paorission, edited by J. Anderson Ashum, is a 25-page booklet dealing specifically with the functional aspects of engineering. It should be of great assistance to students who, having decided to follow engineering as a life work, are still at a loss as to what particular work are still at a loss as to what particular ediction. The Mindgam Technic, Gollege of Engineering, University of Michigan.— 25 cents.

TRE SINCOTTA'S BULL, 1940 edition, is a 512-page catalog that illustrates and describes 15,000 items covering guns, accesores, gun tool, ammunition, and all the other gadgets dear to the heart of the gun hobbyist. This one book might almost be called the equivalent of a whole gun library sunce it can serve as a gude to practically everything in which the reader would be interested. Stoeger Arms Corporation, 507 Fifth Avenue at 42nd Street, New York, New York—4100.

Kodakasome, Protocarbet in Color, is a Spage booklet which discusses Kodachrome film, and gives data on its use for
idicolor finling. Exposure technique
both in daylight and artificial light is
treated, and advice on using a photoelectric
exposure meter is included. A number of
the illustration are in color. Estiman
Kodak Company, Rochester, New York—
25 cents.

THE BROWNING PRESELECTOR AND VISUAL FREQUENCY MONITOR IS a single page leaflet, Bulletin 103-A, which describes two instruments of great value to the serrous anateur radio operator. The preselector described has a general coverage of 5 to 185 meters, with electrical band spread, and grea 25 to 70 BB gain on all bands. The visual frequency monitor insures precise frequency measurement on the anateur bands. Browning Laboratories Incorporated, Winchester, Measuchaustics—Craits.

STATISTICS OF RAUMATS OF CLASS I, is a 12 sheet folded bulletin based on the official summaries of the Interestate Commerce Commission from 1926 to 1938. It covert—among other phases—investment and income, fixed charges and dividends, varieties averages, orgulapment and service, Railworp, Bureau of Raulworp Economics, Railworp, Bureau of Raulworp Economics, Washington, D. Crostis as long as limited supply lasts.

AO PROPAZE is a 25-page hooklet which gives a comprehensive picture of the world's oldest and largest optical institution and of the people who work for it. Well-liburated, the booklet was created by American Optical Company for distribution to prospective employees, company visitors, editors. Although the booklet can be read in a few minutes, the reader will nevertheless get minutes, the reader will nevertheless get

as scourse idea of the condition behindful optical concerns and its work-way said, this as understanding of the intrinsate technical problems involved in the insulanteurier of optical equipment of all kinds. The issolder can be considered a valuable contribution to the art of establishing corollal relationships between industry and the public and as such may well be worth studying. American Confession, Company, Scathfridge, Mean.

LETTZ BOOKLET No. 7838 describes the Lettz Gnome II home projector for two by two-inch slides and gives complete information on the projector and accessories. E. Lettz, Inc., 730 Fifth Avenue, New York, N. Y.—Gratie.

SOME CEASMIC MANUFACTURING DEVELOP-MANTS OF THE WESTERE ELECTRIC COM-PANY, by A. G. Johnson and L. I. Shaw, is a 25-page illustrated report which gives a general picture of the development work in implyed in the introduction of manufacturing processes for various ceramics as used in telephone apparatus. The work reported here should be of interest to many other mountaria fields. Bell Telephone Laboratones, 451 Feu Sireet, New York City— Lunted free daturbution.

BLASTING DYCLESS WITH EXPLOSUES in a \$\partial \text{Partial Partial
Allist-Cratamers Texnore Davies and Lo-Manytenance Morons is a 28-page illutrated catalog that shows various types of industrial drives and gives data on how a drive should be selected for a particular purpose. It also lists various types of elotric motors which are particularly adaptable to varying operating conditions. Allis-Chalmers, Mikusukee, Wisconsin.—Gratis.

EARLY FIRE-MAKING METHODS AND DEVCES, by Warren N. Watson, B.S., A.M., is an interesting book of 'I' pages plus an index which gives a running story of the whole history of fire-making from the most primatic implements of early man and more modern but uncivilized races down to the present day match. Historical and described are fire drills of races down to the present day match. Historical and described are fire drills of the second of the Farren N. Fatton, Edifyst, Virginia— \$150 cloth, \$1.00 paper.

KORAK PILMS in a 56-page booklet on Kodak roll films, filmpsedes, ministures and shysic films. Photographic characteristics of the films, such as speed, contrast, and the lifts, are desembed, and the sensimentic terms are explained. Of expected value in the "Specifications" section, which provides full information as so the photographic said physical disconsistentics, the west and gravcesting of each film. Examon Robile Comp. pays, Rocketter, New York—15 comm.

Patent, Trade Mark, and Related Legal Proceedings That May Have a Direct Effect on Your Business

By ORSON D. MUNN, Litt.B., L.L.B., Sc.D.

New York Bar

UNDRAMATIC

A SET of rules is not a dramatic theme er the copyright laws. This principle is illustrated by a suit for copyright infringement, brought by the author of a book relating to sales arguments, against a prominent automobile manufacturer. It was charged by the author that the copyright on his book was infringed by a moving nicture used by the automobile manufacturer for demonstrating proper sales tech-nique to its salesmen. The portion of the book which was alleged to be infringed contained a list of six principles or rules of persuasion to be followed in presenting a sales argument. The accused moving picture film depicted three salesmen, two of whom expounded and demonstrated faulty sales arguments. The third salesman expounded and illustrated the proper sales approach and correct sales arguments. In the course of his portrayal the salesman listed certain rules or principles to be followed in presenting a sales argument and the rules thus expounded in the moving picture were similar both in content and in sequence to the six rules listed in the In illustrating the proper sales approach the third salesman carried out or followed the rules which he expounded It was contended by the author of the book that because of the listing of the rules or principles of salesmanship as set forth above and because of their portrayal in the manner described, the moving picture constituted a dramatization of the book and accordingly was an infringement of the copyright thereon.

The Court rejected this contention, point-

ing out first of all that "a set of rules is not a dramatic theme" and that accordingly the moving picture could not be con-sidered a dramatization of the book.

SELLER BEWARE

THE seller of a patent should beware that he does not infringe it because in a suit for infringement of the patent he cannot defend on the grounds that the patent is invalid. In a recent suit for patent inment the inventor of a box for paper fringement the inventor of a box for paper rolls had been an officer of the plaintiff forporation and while in its employ had assigned his patent to the corporation. Subsequently, he severed his connection with the plaintiff corporation and organ-ised the defendant corporation for the purpose of manufacturing and selling boxes for paper rolls. Thereafter the plaintiff pr paper rous. Increater the planting organization sued both the inventor and the defendant corporation, charging patent in-ringement and one of the defenses raised as that the patent was invalid. The Court ruled that the defense of invalidity could not be raised because of the previous relationship between the inventor and the plaintiff corporation and because of the intimate connection between the inventor and the defendant corporation. This suit not only expresses the established principle that the assignor of a patent cannot subsequently question the validity of the patent in a suit brought by the assignee but also carries it one step further and holds that a corporation organized and controlled by the assignor cannot question the validity of the petent.

LACQUER

A PATENT on lacquer consisting of a combination of nitrocellulose and a particular synthetic resin was held valid and infringed in a recent suit for patent infringement which illustrates that the substitution of one ingredient for another may amount to invention. The particular synthetic resin which was mixed with the nstrocellulose was described in the patent as a solution of a glycerol ester of a resin and organic carboxylic acid selected from the group consisting of phthalic, maleic, fumeric, malic, and succinic acids. The Court found that prior to the patent in suit lacquers had been made by mixing nitrocellulose with other types of resin. The Court also found that the particular resin described above was known and had been used for other purposes prior to the patent in suit. It was argued by the defendant that the mere substitution of one resin for another did not amount to invention but was within the range of routine laboratory work and represented mere mechanical skill. On the basis of the evidence introduced in the case, however, the Court concluded that the results obtainable by mixing resins with nitrocellulose could not be predicted, that the production of the lacquer covered by the patent in suit resulted from considerable experiment, and that the lacquer was superior to the lacquers of the prior art. As a result the Court held the patent to be valid.

WEATHER STRIPPING

A PATENT for an all-metal weather stripping which is applied to the window without the use of nails, acrews, or other extraneous fastening means was held to be valid and infringed in a recent suit before the federal courts. The patent in suit disclosed a weather stripping formed of a unitary motal clamping portion adapted to clamp to either the sash or the frame and a resilient motal weather closing strip stateched to the clamparature. The defendant manufacture stripping having a metal clamping portion and a resilient weather closing strip. How ever, the defendant's weather stripping differed from the weather stripping shown in the patent in several respects and it was contended by the defendant that because of these differences his stripping did not infringe the patent. Thus, in the stripping wn in the patent the clamp was fo with an arcuste hooked portion which was not embodied in the defendant's structure. The Court found that plaintiff's weather stripping was new and represented a substantial advance in the art. As a result it concluded that the differences referred to by the defendant were not important and did not avoid infringment.

OUTSMARTED

A RECENT case in the New York State Supreme Court involved a rather novel application of the so-called Fair Trade Act. The Fair Trade Act which has been passed in substantially the same form in most of the states of the Union permits a manufacturer to enter into contracts with his customers, fixing the retail prices at which they may sell commodities bearing his trade mark, name, or brand and provides that knowingly selling commodities beneath the price thus fixed constitutes unfair com-

In the case in question a silk manufacturer ntered into a contract with a dress mar facturer confining the sale of silk bearing the trade mark "Pussy Willow" in the cutting trade to the dress manufacturer who in turn agreed that the retail price of the dresses made from the "Pussy Willow" fabric should not be less than \$12.95. A prominent New York department store attempted to purchase dresses made from the "Pussy Willow" fabric from the dress manufacturer but since the department store would not agree to refrain from selling the dresses for less than \$12.95 each, the dress manufacturer refused to sell the dresses to the department store. Thereafter, the department store obtained dresses from another and unauthorized source hut which were nevertheless manufactured from genuine "Pussy Willow" fabric and they proceeded to sell the dresses for less than \$12.95 each. The silk and dress manufacturers then sought to obtain an injunction against the department store on the grounds that the sale of the dresses for less than \$12.95 each was in violation of the Fair Trade Act and constituted unfair competi-

The Court refused to grant the injunction, pointing out that the dress was manufactured by some other source and was not a product of the dress manufacturer nor did it bear his trade mark, name, or brand-The Court also pointed out that, while the allk was undoubtedly the product of the silk manufacturer, the dress did not constitute a "commodity" produced or owned by the silk manufacturer. The Court, conclud-ing that every act of "outsmarting" does not constitute unfair competition, made the following statement:

"Obviously, the defendant outsmarted the plaintiffs. But the law does not essay to reach every case of outsmarting; nor does every case of outsmarting constitute unfair competition. I recognize the plaintiff's embarrassment and possible loss. But I am unable to perceive that the law here invoked affords them relief."

Are You~

putting your spare time to one of the many who are seeking a new field to en-

seeking a means to save money wherever possible?

If you are, here is a practical solution to your problem.

HOPKINS' CYCLOPEDIA OF

FORMULAS

Is the foundation for the beginning of a fascinating hobby; the groundwork on which to build a practical knowledge of useful chemical facts.

Is the foundation for hundreds of suggestions for those who are seeking salable articles which can be manufactured at home profitably on a small scale.

TF you want to save money on wines and liquors; your dyes, inks, polishes, soaps, paints and varnishes. adhesives, antiseptics, bleaches, cosmetics, etc.

You can profitably make them from the 15000 formulas contained in the 1077 pages of

HOPKINS'

Cyclopedia of Formulas \$5.50 postpaid (domestic)
